Abstract

We study stochastic billiards on general tables: a particle moves according to its constant velocity inside some domain $\mathcal{D} \subset \mathbb{R}^d$ until it hits the boundary and bounces randomly inside according to some reflection law. We assume that the boundary of the domain is locally Lipschitz and almost everywhere continuously differentiable. The angle of the outgoing velocity with the inner normal vector has

a specified, absolutely continuous density. We construct the discrete time and the continuous time processes recording the sequence of hitting points on the boundary and the pair location/velocity. We mainly focus on the case of bounded domains. Then, we prove exponential ergodicity of these two Markov processes, we study their invariant distribution and their normal (Gaussian) fluctuations. Of particular interest is the case of the cosine reflection law: the stationary distributions for the two processes are uniform in this case, the discrete time chain is reversible though the continuous time process is quasi-reversible. Also in this case, we give a natural construction of a chord "picked at random" in $\mathcal{D}$, and we study the angle of intersection of the process with a $(d-1)$-dimensional manifold contained in $\mathcal{D}$.

Keywords: cosine law, Knudsen random walk, Knudsen regime, random chord, Bertrand paradox, kinetic equations, invariant measure, shake-and-bake algorithm

1 Introduction

The purpose of this paper is to provide a rigorous mathematical treatment of a stochastic process that can be informally described as follows. A particle moves with constant speed inside some d-dimensional domain. When it hits the domain boundary, it is reflected in some random direction, not depending on the incoming direction, and keeping the absolute value of its speed. One would like to understand basic stationary and dynamical properties of this process for "physically reasonable" domains and laws of reflection.

Indeed, the current physics motivation for studying this process comes from the need to understand diffusive motion in porous media on a microscopic level. One wishes to explore the random motion of molecules inside pores of nanometer scale in order to deduce large-scale transport properties inside a porous grain. There are numerous applications of this basic problem. Recently, this has emerged as being of considerable importance e.g. in the design of synthetic zeolites for catalysis [17] for which in a computer model a pore-selective molecular traffic control effect has been shown to enhance the effective reactivity of catalytic grains [6].

Inside a pore only very few molecules can reside so that the mean free

path between molecule-molecule collision is rather large. As a result intra-porous mobility is dominated by the interaction of molecules with the pore walls rather than among themselves. This is the so-called Knudsen regime in gas dynamics which gives rise to the model described above in which all molecule-molecule interactions are neglected [18, 8]. As a further simplifying feature the kinetic energy of a particle is strictly conserved. Due to a complicated microscopic structure of the pore walls momentum is assumed to be transferred in a memoryless random fashion.

Already Martin Knudsen proposed the cosine reflection law, in which case the reflected direction has a rotation-invariant cosine distribution around the surface normal. This is in some sense a physically natural choice (Feres and Yablonsky [13, 14]) and has attracted very considerable interest in recent years, see e.g. Coppens and collaborators [9, 10, 21], and also [26]. In particular, it has been debated whether or not the self-diffusion coefficient (defined by the mean-square displacement of a particle) and the transport diffusion coefficient (defined via the density gradient between two open boundaries of a pore) coincide in the case of the Knudsen cosine law and how these diffusivities depend on the structure of the pore walls. In two space dimensions the large scale motion of a particle inside a strip of constant width is analytically argued to be superdiffusive.

The results reported in [9, 10, 21, 26] on diffusion in more complicated pore surfaces are mostly numerical simulation results for open pores where particles are injected and extracted. This numerical evidence, however, has proved to be subtle and often ambiguous, much depending on details of the definition of the quantities under consideration, which are frequently not provided. In order to clarify some of these open issues and for making further progress we provide here a mathematically rigorous treatment. In the present paper we focus on bounded domains which also prepares the ground for addressing the problems arising in future study of open domains. Pores in real solids such as zeolites have a rather complicated surface structure which is usually not known in great detail. Hence we keep our discussion as general as possible as far as the domain boundary and the reflection law is concerned. Nevertheless, particular emphasis is given to the previously studied Knudsen cosine reflection law.

Next, we discuss related papers from the probabilistic literature. Motivated by an asymptotically minimax strategy for the so-called "princess and monster" game, stochastic billiards with the cosine law were considered by Lalley and Robbins [19, 20] on a convex domain of the plane, and the invari-

ant measure for the position was found to be uniform. Later on, billiards have been used in Monte Carlo Markov chains algorithms by Borovkov [4, 5] and Romeijn [25] (where the stochastic billiard with the cosine law of reflection appears as "running shake-and-bake algorithm") to generate random vectors in a connected domain with smooth boundary or on the boundary itself. S. Evans [11] gives a detailed account of the case of uniform reflection law and of a domain with $\mathcal{C}^1$ boundary or a polygon. We emphasize that the present paper improves much on the geometry of the domain.

From an analytical perspective, Bardos, Golse and Colonna [1] and Boatto and Golse [3] consider a gas of particles moving along straight lines between two infinite parallel horizontal planes, where the reflection angle is given by some dynamical system. They prove a diffusion limit in this model where there exists a natural angular cut-off. For some other models with deterministic behaviour inside the domain and stochastic behaviour on the boundaries, see Goldstein, Kipnis and Ianiro [15] and Caprino and Pulvirenti [7].

We now briefly describe the content of this paper. It turns out to be useful to distinguish the random motion of the particle (below referred to as stochastic billiard) from the stochastic process defined by the sequence of hits of the particle at the boundary (below referred to as random walk). We consider domains which boundary is almost everywhere continuously differentiable and satisfies a Lipschitz condition. We first construct the walk and the billiard on such general domains. We then focus on bounded domains. For general reflection laws, we prove for both processes existence and uniqueness of an invariant probability measure, convergence to it, and a central limit theorem. A key observation is that these Markov processes satisfy the Döblin condition.

The special case of the cosine law for the reflection, presents some interesting probabilistic, dynamic and geometric properties. The invariant measures are uniform, the random walk is reversible, as well as the stochastic billiard up to a sign change in the speed. The cosine law also yields a construction of a "chord picked at random" in the domain, which has universality properties independently of the domain. The mean chord length is equal, up to an universal constant factor, to the volume–to–surface ratio of the domain. Also, for a smooth convex subdomain, our random chord induces a random chord on the subdomain, simply by its trace (conditionally on a non-empty intersection): we prove that the law of this trace coincides with our construction of a random chord when directly performed on the subdomain. With a view on future applications to open systems we finally establish some statistical

property of the particle when it crosses a surface inside the domain.

This paper is organized as follows. In Section 2 we define the model, comment on conditions for "good" behaviour and state our main results. Then, in Section 3 we establish some auxiliary results related mainly to geometric properties of domains with Lipschitz boundary. Our main results are proved in Section 4 (discrete time), Section 5 (continuous time) and Section 6 (geometric properties of the random chord).

2 Formal definitions and main results

In Section 2.1 we describe the general conditions imposed on the domain $\mathcal{D}$ and we introduce some notation related to this domain. In Section 2.2 the discrete time and continuous time processes are formally defined, and we discuss conditions under which the processes exist or have good behavior. The results are formulated in Section 2.3.

2.1 General notations and standing assumptions

Let $\|\cdot\|$ be the Euclidean norm in $\mathbb{R}^d$, and define $\mathcal{B}(x,\varepsilon) = \{y \in \mathbb{R}^d : \|x-y\| < \varepsilon\}$ to be the open ε-neighborhood of $x \in \mathbb{R}^d$, and $\mathbb{S}^{d-1} = \{y \in \mathbb{R}^d : \|y\| = 1\}$ to be the unit sphere. Consider an open connected domain $\mathcal{D} \subset \mathbb{R}^d$, and let $\partial\mathcal{D}$ be the boundary of $\mathcal{D}$, and $\bar{\mathcal{D}}$ be the closure of $\mathcal{D}$ (so that $\mathcal{D} \cup \partial\mathcal{D} = \bar{\mathcal{D}}$). In this paper we will deal with three reference measures:

- the d-dimensional Lebesgue measure on $\mathcal{D}$ or $\bar{\mathcal{D}}$,
- the Haar measure on the sphere $\mathbb{S}^{d-1}$,
- the $(d-1)$-dimensional Hausdorff measure in $\mathbb{R}^d$ restricted to $\partial\mathcal{D}$.

To simplify notations we will use the same symbols $dx, dv, dz, \ldots$ to denote all of them. We warn the reader, and we recall that ambiguity on the measures under consideration – should it arise – can be easily resolved by checking the space of integration. Similarly, when we write $|A|$, this corresponds to the d-dimensional Lebesgue measure of A in the case $A \subset \mathcal{D}$, and to the $(d-1)$-dimensional Hausdorff measure of A in the case $A \subset \partial\mathcal{D}$.

Throughout this paper we suppose that $\partial\mathcal{D}$ is a $(d-1)$-dimensional surface satisfying the Lipschitz condition. This means that for any $x \in \partial\mathcal{D}$ there

exist $\varepsilon_x > 0$, an affine isometry $\mathfrak{I}_x : \mathbb{R}^d \to \mathbb{R}^d$, a function $f_x : \mathbb{R}^{d-1} \to \mathbb{R}$ such that

- f_x satisfies Lipschitz condition, i.e., there exists a constant $L_x > 0$ such that $|f_x(z) - f_x(z')| < L_x\|z - z'\|$ for all z, z' (without restriction of generality we suppose that $L_x > 1$);
- $\mathfrak{I}_x x = 0$, $f_x(0) = 0$, and

$$\mathfrak{I}_x(\mathcal{D} \cap \mathcal{B}(x, \varepsilon_x)) = \{z \in \mathcal{B}(0, \varepsilon_x) : z^{(d)} > f_x(z^{(1)}, \dots, z^{(d-1)})\}.$$

Recall that, by Rademacher's theorem (cf. e.g. [12, theorem 3.1.6]), the Lipschitz condition implies that the boundary $\partial\mathcal{D}$ is a.e. differentiable. This, however, is not enough for our purposes, so we assume additionally that the boundary is a.e. *continuously* differentiable, and we denote by $\tilde{\mathcal{R}} \subset \partial\mathcal{D}$ the set of boundary points where $\partial\mathcal{D}$ is continuously differentiable. That is, we suppose that $\tilde{\mathcal{R}}$ is open (with respect to the induced topology on $\partial\mathcal{D}$), such that the $(d-1)$-dimensional Hausdorff measure of $\partial\mathcal{D} \setminus \tilde{\mathcal{R}}$ is equal to zero, and $\partial\mathcal{D}$ has locally $\mathcal{C}^1$ parametrization in any point of $\tilde{\mathcal{R}}$.

For all $x \in \tilde{\mathcal{R}}$ we can define a unique vector $\mathbf{n}(x) \in \mathbb{S}^{d-1}$ with the following properties:

(i) for all small enough $\varepsilon > 0$ we have that $x + \varepsilon\mathbf{n}(x) \in \mathcal{D}$,

(ii)
$$\inf_{y \in \mathcal{B}(x,\delta) \cap \partial\mathcal{D}} (y - x) \cdot \mathbf{n}(x) = o(\delta) \qquad \text{as } \delta \to 0$$

(i.e., $\mathbf{n}(x)$ is the normal vector which points inside the domain). Clearly, the map $x \to \mathbf{n}(x)$ is continuous for all $x \in \tilde{\mathcal{R}}$.

Let $x \cdot y$ be the scalar product of x and y. For any $u, v \in \mathbb{S}^{d-1}$ we define by

$$\varphi(u, v) = \arccos(u \cdot v)$$

the angle between u and v, and by

$$\mathbb{S}_v = \{w \in \mathbb{S}^{d-1} : v \cdot w > 0\}$$

the half-sphere looking in the direction v. If $u \in \mathbb{S}_{\mathbf{n}(x)}$, we use a simplified notation $\varphi_x(u) := \varphi(u, \mathbf{n}(x)) \in [0, \pi/2)$.

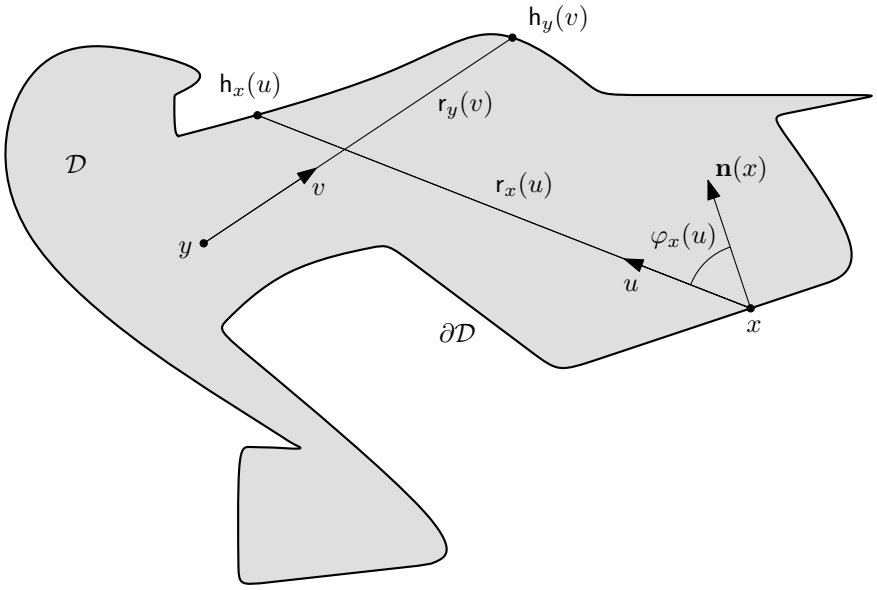

Figure 1: On the definition of the quantities $\varphi_x(u)$, $\mathsf{r}_x(u)$ and $\mathsf{h}_x(u)$

Note that, by definition of $\mathbf{n}(x)$, if $u \in \mathbb{S}_{\mathbf{n}(x)}$ then for all small enough $t > 0$ it holds that $x + tu \in \mathcal{D}$. Using this fact, for any pair (x, u) such that either $x \in \tilde{\mathcal{R}}$, $u \in \mathbb{S}_{\mathbf{n}(x)}$, or $x \in \mathcal{D}$, $u \in \mathbb{S}^{d-1}$, define by (see Figure 1)

$$\mathsf{r}_x(u) = \inf\{t > 0 : x + tu \in \partial\mathcal{D}\} > 0$$

the distance from x to $\partial\mathcal{D}$ along the direction u (we use the convention $\inf \emptyset = +\infty$), and by

$$\mathsf{h}_x(u) = x + u\mathsf{r}_x(u) \in \{\partial\mathcal{D}, \infty\}$$

the point on $\partial\mathcal{D}$ seen from x in that direction (in fact, $\mathsf{h}_x(u) = \infty$ if and only if $\mathsf{r}_x(u) = +\infty$).

2.2 Construction of the walk and billiard

In this section we define the main objects of interest, the continuous time random motion on $\bar{\mathcal{D}}$ described informally above, and its skeleton random walk, i.e., the discrete-time Markov chain corresponding to the sequence of points where the continuous time process hits $\partial\mathcal{D}$.

Denote by $e = (1, 0, \ldots, 0)$ the first coordinate vector. Let $\eta = (\eta_n, n = 1, 2, \ldots)$ be a sequence of i.i.d., $\mathbb{S}_e$-valued random vectors with absolutely continuous distribution on $\mathbb{S}_e$: there is a function $\bar{\gamma}$ such that for any measurable $B \subset \mathbb{S}_e$ it holds that $\mathbf{P}[\eta \in B] = \int_B \bar{\gamma}(u)\, du$ (where $\mathbf{P}$ stands for the probability). We suppose that $\bar{\gamma}$ is supported on $\mathbb{S}_e$ in the sense that

$$\inf_{u \in B} \bar{\gamma}(u) > 0 \tag{1}$$

for any compact $B \subset \mathbb{S}_e$.

To define the model, we need also a family $(U_x, x \in \partial\mathcal{D})$ of unitary linear operators in $\mathbb{R}^d$ with the property $U_x e = \mathbf{n}(x)$ for all $x \in \tilde{\mathcal{R}}$, so that U_x is a rotation of $\mathbb{S}^{d-1}$ which sends e to $\mathbf{n}(x)$. Here, two cases need to be considered separately.

- Case 1: the function $\bar{\gamma}$ is rotationally symmetric around the first coordinate axis, i.e, $\bar{\gamma}(u_1) = \bar{\gamma}(u_2)$ whenever $u_1 \cdot e = u_2 \cdot e$. In this case we do not need any additional assumptions on the family $(U_x, x \in \partial\mathcal{D})$ except measurability of $x \mapsto U_x$, and we denote $\mathcal{R} := \tilde{\mathcal{R}}$.

- Case 2: the function $\bar{\gamma}$ is not symmetric. In this case we assume also that the map $x \to U_x$ is continuous for almost all $x \in \partial\mathcal{D}$, and we define $\mathcal{R} = \{x \in \tilde{\mathcal{R}} :$ the map $x \to U_x$ is continuous in $x\}$.

Fix an arbitrary $x_0 \in \mathcal{R}$; using the sequence $(\eta_n, n \geq 1)$, we define a discrete time Markov chain $(\xi_n, n = 0, 1, 2, \ldots)$ and a continuous time process $(X_t, t \geq 0)$, so-called *stochastic billiard*, in the following way. Below, $\mathfrak{S}$ stands for a special state, that we allow for technical reasons, ξ_n or $X_t = \mathfrak{S}$ means that the corresponding process is undefined.

(i) Put $\xi_0 = x_0$. Inductively, we define $\xi_{n+1} \in \{\partial\mathcal{D}, \infty, \mathfrak{S}\}$ as follows:

$$\xi_{n+1} = \begin{cases} \mathsf{h}_{\xi_n}(U_{\xi_n}\eta_n), & \text{if } \xi_n \in \mathcal{R}, \\ \mathfrak{S}, & \text{if } \xi_n = \mathfrak{S} \text{ or } \xi_n \in \partial\mathcal{D} \setminus \mathcal{R}, \\ \infty, & \text{if } \xi_n = \infty. \end{cases}$$

Since η_n has a density, one can show (see Lemma 3.2 below) that for any $x \in \mathcal{R}$, the distribution of $\mathsf{h}_x(U_x\eta)$ is absolutely continuous with respect to the $(d-1)$-dimensional Hausdorff measure on $\partial\mathcal{D}$. Since almost all points of $\partial\mathcal{D}$ belong to $\mathcal{R}$, almost surely it holds that either $\xi_n \in \partial\mathcal{D}$ for all n, or there exists some n_0 such that $\xi_{n_0} = \infty$.

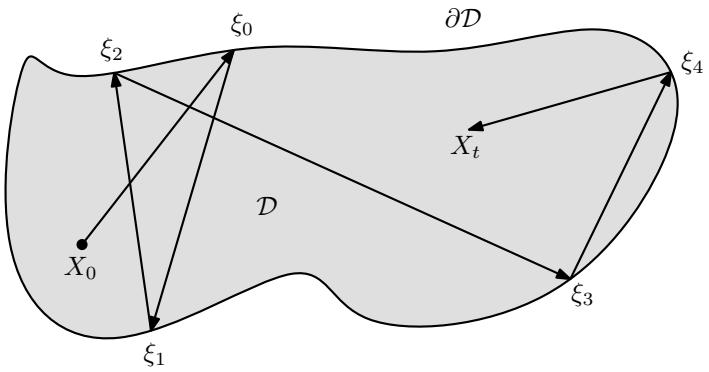

Figure 2: A stochastic billiard starting from the interior of $\mathcal{D}$

(ii) Again, we put $X_0 = x_0$, and let us abbreviate $\tau_0 := 0$ and

$$\tau_n = \sum_{i=0}^{n-1} \mathsf{r}_{\xi_i}(U_{\xi_i}\eta_i),$$

$n = 1, 2, \ldots$ (formally, if $\xi_k = \mathfrak{S}$ for some k, we put $\tau_{k'} = \tau_k$ for all $k' \geq k$). Then, for $t \in [\tau_n, \tau_{n+1})$ define

$$X_t = \xi_n + (t - \tau_n)U_{\xi_n}\eta_n.$$

Since a.s. the random walk never enters $\partial\mathcal{D} \setminus \mathcal{R}$, we obtain that, with probability 1, $X_t \in \bar{\mathcal{D}}$ is well defined for all $t \in [0, \lim_{n\to\infty} \tau_n)$.

Intuitively, the Markov chain ξ can be described as follows: on each step, the particle chooses the direction of the jump according to the density $\bar{\gamma}$ "turned" in the direction of the normal vector (the one that looks inside the domain $\mathcal{D}$), and then instantly jumps to the point on the boundary of $\mathcal{D}$ seen in this direction. As a process on the boundary of $\mathcal{D}$, it is as close as possible to a random walk, and we will denote it like that. For some unbounded domains it may happen, of course, that such a point does not exist, in which case the particle jumps directly to the infinity. For the stochastic billiard X, when on the boundary, the particle uses the same procedure to choose the direction, but then it moves with speed 1 until it hits the boundary again (if it ever does).

Let us note that we can define the stochastic billiard starting in any $x_1 \in \mathcal{D}$ as well (in this case we have to specify also the initial direction), see

Figure 2. Of course, one may consider the random walk ξ starting from any initial distribution on $\partial\mathcal{D}$ (one has to require that the probability that the starting point belongs to $\mathcal{R}$ is 1); similarly, one may consider the stochastic billiard X starting from any initial distribution on $\mathcal{D} \times \mathbb{S}^{d-1}$ (and, in fact, we will frequently do that in this paper).

The next proposition shows that, supposing that the boundary of the domain satisfies the Lipschitz condition, the process X_t is well defined for all $t \geq 0$.

Proposition 2.1 *With probability* 1, $\lim_{n\to\infty} \tau_n = +\infty$.

It would be interesting to consider more general laws of reflection: for example, one can suppose that the law of η is continuous, but is not supported on the whole $\mathbb{S}_e$; and/or one can suppose that the law of η has discrete and/or singular components. However, this would bring in some substantial technical difficulties. For instance, in the former case the domain may be such that some parts of the boundary are not seen from any of the boundary points (since we no longer have the rule "if the particle can go from x to y, then it can go from y to x"). In the latter case, there is an additional difficulty that, even if $x \in \mathcal{R}$, it may happen that $\mathbf{P}[\mathsf{h}_x(U_{\mathbf{n}(x)}\eta) \in \mathcal{R}] < 1$, and so one needs to define the set $\mathcal{R}$ differently (to ensure that with probability 1 the random walk never leaves the set $\mathcal{R}$), and show that, with that new definition, we still have $|\partial\mathcal{D} \setminus \mathcal{R}| = 0$.

We end this subsection by commenting our assumption that the boundary satisfies Lipschitz condition. If one considers domain with the boundary which is not everywhere continuously differentiable (even if one supposes that it is not differentiable in only one point), then the Döblin condition (23) below need not be satisfied when the boundary is non-Lipschitz (for instance, it is not satisfied for the domain in Figure 3). So, although it can be indeed interesting to study stochastic billiards on such domains, this task is much more difficult due to the lack of geometric ergodicity and related properties (in [4] it was claimed that the results there are valid for domains with boundary consisting of a finite number of smooth surfaces; on the other hand, Theorem 1 of [4] is wrong for e.g. the domain of Figure 3). Also, without Lipschitz condition it is not even clear if the process X_t is well defined for all $t \geq 0$. If the density $\bar{\gamma}$ is not symmetric, there are examples (cf. the one below) when the random walk ξ_n converges to a (singular) point on the boundary. It is, in our opinion, a challenging problem to find out if such examples exist for symmetric laws of reflection.

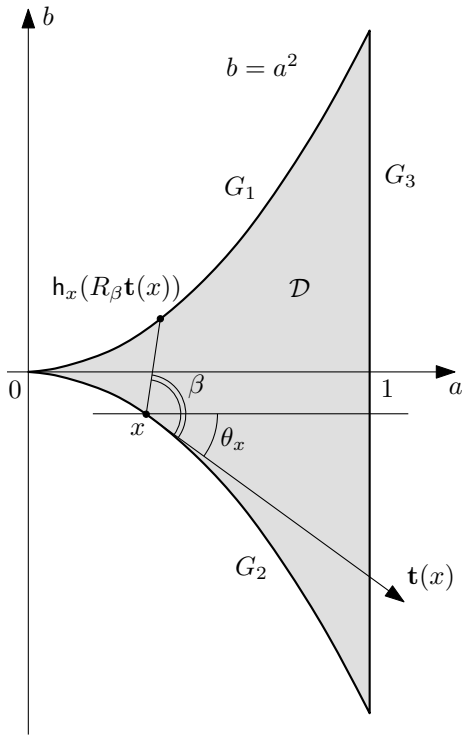

Figure 3: A stochastic billiard on a non-Lipschitz domain

Example (Non-Lipschitz boundary). Consider the domain

$$\mathcal{D} = \{(a,b) \in \mathbb{R}^2 : 0 < a < 1, -a^2 < b < a^2\}$$

(see Figure 3). We denote by

$$\begin{aligned} G_1 &= \{(a,b) \in \mathbb{R}^2 : 0 \le a < 1, b = a^2\}, \\ G_2 &= \{(a,b) \in \mathbb{R}^2 : 0 < a < 1, b = -a^2\}, \\ G_3 &= \{(a,b) \in \mathbb{R}^2 : a = 1, 0 \le b \le 1\}, \end{aligned}$$

the three smooth pieces of the boundary, so that $\partial\mathcal{D} = G_1 \cup G_2 \cup G_3$. Let $x = (x_1, -x_1^2) \in G_2$ be a point on the lower part of the boundary, and abbreviate $\theta_x = \arctan(2x_1)$ (we use the same notation for $x = (x_1, x_1^2) \in G_1$ as well). Let R_β be the operator of anticlockwise rotation by angle $\beta \in [0, \pi]$, and J be the symmetry operator defined by $J(a,b) = (-a,b)$. The family of operators $(U_x, x \in \partial\mathcal{D})$ is then defined as follows: $U_x = R_{\frac{\pi}{2}+\theta_x} J$ for $x \in G_1$, $U_x = R_{\frac{\pi}{2}-\theta_x}$ for $x \in G_2$, $U_x = J$ for $x \in G_3$.

Let $g(x)$ be the first coordinate of $x \in \mathbb{R}^2$. Define, for $x \in G_1 \bigcup G_2$,

$$D_x(\beta) = g(\mathsf{h}_x(R_\beta \mathbf{t}(x))) - g(x),$$

where $\mathbf{t}(x)$ is the tangent unit vector at x with positive first coordinate.

After some elementary computations, one can obtain the following for small enough x:

- $D_x(\beta) \leq 1$ for $\beta < 8x_1$,
- $D_x(\beta) \leq \frac{8x_1^2}{\beta}$ for $\beta \in [8x_1; \frac{\pi}{2} + \theta_x]$,
- $D_x(\beta) \leq 0$ for $\beta \in [\frac{\pi}{2} + \theta_x; \frac{3\pi}{4} + \theta_x]$,
- $D_x(\beta) \leq -\frac{2x_1^2}{3}$ for $\beta > \frac{3\pi}{4} + \theta_x$.

Consider the following density on $\mathbb{S}_e$: being β the angle between the element of $\mathbb{S}_e$ and $(-e_2)$, write (with some abuse of notation) $\bar{\gamma}(\beta) = \frac{4}{\pi^4}\beta^3$, $\beta \in (0, \pi)$. Since

$$\mathbf{E}(g(\xi_{n+1}) - g(\xi_n) \mid \xi_n = x) = \frac{4}{\pi^4} \int_0^\pi D_x(\beta)\beta^3 \, d\beta,$$

one sees from the above above properties of $D_x(\beta)$ that

$$\mathbf{E}(g(\xi_{n+1}) - g(\xi_n) \mid \xi_n = x) \leq 0 \tag{2}$$

for all small enough x. Define $\sigma(y_0) = \min\{n : g(\xi_n) \geq y_0\}$. The equation (2) means that, for small enough y_0, the process $g(\xi_{n\wedge\sigma(y_0)})$ is a supermartingale. So, there exists $g_\infty = \lim_{n\to\infty} g(\xi_{n\wedge\sigma(y_0)})$, and, by the Fatou lemma we have $\mathbf{E}g_\infty \leq \mathbf{E}g(\xi_0)$. If $\xi_0 < y_0$, this implies that $\sigma(y_0) = \infty$ with positive probability, and then with a little more work one concludes that

$$\xi_n \longrightarrow 0 \text{ a.s. as } n \to \infty.$$

It seems clear that one should be able to construct examples of such kind where it holds also that $\lim_{n\to\infty} \tau_n < \infty$. However in this particular example it is rather difficult to find out whether this happens, so we opted for not discussing it here. Anyway, existence of such examples is already a good reason to assume that the boundary of the domain satisfies the Lipschitz condition. □

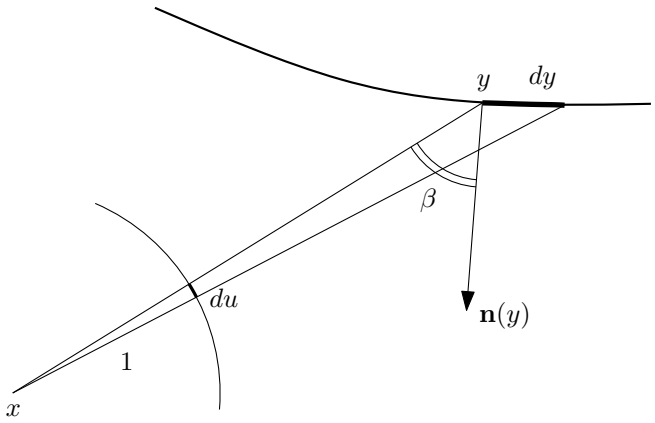

Figure 4: $du = \|x-y\|^{d-1} \cos\beta \, dy$

2.3 Main results

For the rest of this paper, we suppose that $\mathcal{D}$ is a bounded domain (that is, $\mathrm{diam}(\mathcal{D}) < \infty$). Note that the Lipschitz condition on the boundary implies that in this case it holds that $|\partial\mathcal{D}| < \infty$ and that the number of connected components of $\partial\mathcal{D}$ is finite, see Lemma 3.1 below.

For any $x, y \in \mathbb{R}^d$, $x \neq y$, let us define the vector $\ell_{x,y} = \frac{y-x}{\|y-x\|} \in \mathbb{S}^{d-1}$; note that $\ell_{x,y} = -\ell_{y,x}$. We say that $y \in \bar{\mathcal{D}}$ is *seen from* $x \in \bar{\mathcal{D}}$ if there exists $u \in \mathbb{S}^{d-1}$ and $t_0 > 0$ such that $x + tu \in \mathcal{D}$ for all $t \in (0, t_0)$ and $x + t_0 u = y$. Equivalently, the open segment (x, y) lies in $\mathcal{D}$ and $x \neq y$. Clearly, if y is seen from x then x is seen from y, and we write "$x \leftrightarrow y$" when this occurs.

From the definition of the Markov chain ξ_n, we will show that the transition kernel can be written

$$\mathbf{P}[\xi_{n+1} \in A \mid \xi_n = x] = \int_A K(x,y)\, dy \ ,$$

where (see Figure 4)

$$K(x,y) = \frac{\bar{\gamma}(U_x \ell_{x,y}) \cos\varphi_y(\ell_{y,x})}{\|x-y\|^{d-1}} \mathbf{1}\{x, y \in \mathcal{R}, x \leftrightarrow y\} \tag{3}$$

is the transition density. Formally, if x or y does not belong to $\mathcal{R}$, we put $K(x,y) = 0$.

As mentioned above, we consider separately the important case of the cosine law of reflection

$$\bar{\gamma}(u) = \gamma_d \cos\varphi(e,u) = \gamma_d e \cdot u, \tag{4}$$

where the normalization constant γ_d is defined by

$$\gamma_d = \Big(\int_{\mathbb{S}_e} \cos\varphi(e,u)\, du \Big)^{-1} = \Big(\int_{\mathbb{S}_e} u \cdot e\, du \Big)^{-1} ,$$

making $K(x,\cdot)$ a probability density on $\partial\mathcal{D}$ for all $x \in \mathcal{R}$. The transition density then becomes

$$\begin{aligned} \tilde{K}(x,y) &= \frac{\gamma_d \cos\varphi_x(\ell_{x,y}) \cos\varphi_y(\ell_{y,x})}{\|x-y\|^{d-1}} \mathbf{1}\{x,y \in \mathcal{R}, x \leftrightarrow y\} \\ &= \frac{\gamma_d \big((y-x)\cdot \mathbf{n}(x)\big)\big((x-y)\cdot \mathbf{n}(y)\big)}{\|x-y\|^{d+1}} \mathbf{1}\{x,y \in \mathcal{R}, x \leftrightarrow y\} \end{aligned}$$

When considering the specific case of the cosine law of reflection, we write $\tilde{\xi}, \tilde{X}$ instead of ξ, X, and we call these processes *Knudsen random walk* (KRW) and *Knudsen stochastic billiard* (KSB).

Define $\hat{\mu}_0$ to be the "uniform" probability measure on $\partial\mathcal{D}$: $\hat{\mu}_0(A) = \frac{|A|}{|\partial\mathcal{D}|}$. Since $\tilde{K}(x,y)$ is symmetric, we immediately obtain that the KRW $\tilde{\xi}$ is reversible, with the reversible (and thus invariant) measure $\hat{\mu}_0$. For other reflection laws it is usually not easy to find the exact form of the invariant measure (except for some particular cases, see [11]), but nevertheless we prove that such a measure exists and is unique, the random walk converges to it exponentially fast, and the Central Limit Theorem holds.

Theorem 2.1 *Suppose that* $\operatorname{diam}(\mathcal{D}) < \infty$.

(i) There exists a unique probability measure $\hat{\mu}$ on $\partial\mathcal{D}$ which is invariant for the random walk ξ_n. Moreover, there exists a function $\psi : \partial\mathcal{D} \to \mathbb{R}_+$ such that $\hat{\mu}(A) = \int_A \psi(x)\, dx$ which satisfies

$$\psi(x) = \int_{\partial\mathcal{D}} \psi(y) K(y,x)\, dy. \tag{5}$$

Finally, the density ψ can be chosen in such a way that $\inf_{\partial\mathcal{D}} \psi > 0$.

(ii) There exist positive constants β_0, β_1 (not depending on the initial distribution of ξ_0) such that

$$\|\mathbf{P}[\xi_n \in \cdot] - \hat{\mu}\|_{\mathsf{v}} \le \beta_0 e^{-\beta_1 n}, \tag{6}$$

where $\|\cdot\|_{\mathsf{v}}$ is the total variation norm.

(iii) We have the Central Limit Theorem: for any measurable $A \subset \partial\mathcal{D}$ there exists σ_A, with $\sigma_A > 0$ if $0 < |A| < |\partial\mathcal{D}|$, such that

$$n^{-1/2}\Big(\sum_{i=1}^{n} \mathbf{1}\{\xi_i \in A\} - n\hat{\mu}(A)\Big) \tag{7}$$

converges in distribution to a $\mathrm{Normal}(0, \sigma_A^2)$ *random variable.*

In particular, for the KRW, (6) and (7) hold with $\hat{\mu} = \hat{\mu}_0$.

We remark that the relation (5) for the Radon-Nykodim density ψ of the invariant measure $\hat{\mu}$ is what is usually called the balance condition.

Contrary to ξ_n, the process X_t by itself is not Markovian, which, in principle, makes it more difficult to analyze. To overcome that difficulty, we define another process V_t by

$$V_t = \lim_{\varepsilon \downarrow 0} \frac{X_{t+\varepsilon} - X_t}{\varepsilon}.$$

Clearly, $V_{t_1} = V_{t_2} = U_{\xi_{n-1}}\eta_{n-1}$ for all $t_1, t_2 \in [\tau_{n-1}, \tau_n)$. In words, V_t is the càdlàg version of the motion direction (or speed vector) of the stochastic billiard process at time t. As before, for the particular case of the cosine reflection law, we write $\tilde{V}$ instead of V.

Now, it is clear that the pair (X_t, V_t) is a Markov process. Associated to this Markov process there is a whole family of martingales. Introduce the sigma-field $\mathfrak{F}_t$ generated by $X_s, V_s, s \in [0, t]$, and $\mathcal{L}$ the transport operator

$$\mathcal{L}f(x, v) = v \cdot \nabla_x f.$$

Let $\mathcal{C}^{1,0}(\bar{\mathcal{D}} \times \mathbb{S}^{d-1})$ be the set of functions on $\bar{\mathcal{D}} \times \mathbb{S}^{d-1}$ which are continuous and once continuously differentiable in the first variable on $\bar{\mathcal{D}} \times \mathbb{S}^{d-1}$.

Proposition 2.2 *Let $f \in \mathcal{C}^{1,0}(\bar{\mathcal{D}} \times \mathbb{S}^{d-1})$ such that*

$$f(x, v) = \int_{\mathbb{S}_e} f(x, U_x u)\bar{\gamma}(u)du \qquad \forall x \in \mathcal{R}, v \cdot \mathbf{n}(x) \leq 0. \tag{8}$$

Then,

$$f(X_t, V_t) - \int_0^t \mathcal{L}f(X_s, V_s)ds \tag{9}$$

is a martingale with respect to $(\mathfrak{F}_t; t \geq 0)$.

From this, it follows that the generator of the Markov process $(X_t, V_t; t \geq 0)$ is given by $\mathcal{L}$ on the set of smooth functions satisfying (8). Note that the left-hand side of (8) does not depend on v provided $x \in \mathcal{R}, v \cdot \mathbf{n}(x) \leq 0$.

Next, we show that the stochastic billiard converges exponentially fast to equilibrium.

Theorem 2.2 *There exist a probability measure χ on $\mathcal{D} \times \mathbb{S}^{d-1}$ and positive constants β_0', β_1' (not depending on the initial distribution of position and direction) such that*

$$\|\mathbf{P}[X_t \in \cdot, V_t \in \cdot] - \chi\|_{\mathsf{v}} \leq \beta_0' e^{-\beta_1' t}, \tag{10}$$

for all $t \geq 0$.

We complement this result with a central limit theorem.

Theorem 2.3 *Let $f : \bar{\mathcal{D}} \times \mathbb{S}^{d-1} \to \mathbb{R}$ be measurable and bounded function. Suppose also that it is centered, that is,*

$$\int_{\bar{\mathcal{D}} \times \mathbb{S}^{d-1}} f(x, v) \chi(dx, dv) = 0. \tag{11}$$

Then, as $t \to \infty$, the random variables

$$t^{-1/2} \int_0^t f(X_s, V_s)\, ds$$

converge in distribution to a Normal$(0, \sigma_f^2)$ *random variable, $\sigma_f^2 \geq 0$.*

Remark. The variance σ_f^2 may be equal to zero for some non-trivial f's. Here is an example for KSB. Let $G : \bar{\mathcal{D}} \to \mathbb{R}$ be a $\mathcal{C}^1$ function, and

$$f(x, v) = -v \cdot \nabla G(x). \tag{12}$$

Then, $\sigma_f^2 = 0$. The proof of this fact is placed in the end of the proof of Theorem 2.3. □

Next, we relate the invariant measure for the stochastic billiard to the one for the skeleton random walk. Recall that, by Theorem 2.1, the measure $\hat{\mu}$ is absolutely continuous with respect to the Hausdorff measure dz on $\partial\mathcal{D}$, and $\psi(z) := \frac{d\hat{\mu}}{dz}(z)$. Let μ_0 and ν_0 be the uniform measures on $\mathcal{D}$ and $\mathbb{S}^{d-1}$ respectively, i.e., $\mu_0(A) = \frac{|A|}{|\mathcal{D}|}$, $\nu_0(B) = \frac{|B|}{|\mathbb{S}^{d-1}|}$.

Theorem 2.4 *The invariant measure χ is absolutely continuous with respect to $\mu_0 \otimes \nu_0$, and is given by*

$$\chi(dx, dv) = \psi(z)\, \frac{\bar{\gamma}(U_z^{-1} v)}{\cos \varphi_z(v)} dx\, dv, \qquad z = \mathsf{h}_x(-v).$$

In particular, the product measure $\mu_0 \otimes \nu_0$ is invariant for KSB $(\tilde{X}_t, \tilde{V}_t)$.

For the rest of this section, we concentrate on the process with the cosine reflection law.

By means of an usual procedure (shift the law of the KSB starting with the stationary measure $\mu_0 \otimes \nu_0$ by $(-T)$, and take the limit as $T \to \infty$) we can define a stationary version of the KSB for all $t \in \mathbb{R}$.

Theorem 2.5 *Let $(\tilde{X}_t, \tilde{V}_t)_{t\in\mathbb{R}}$ be the stationary KSB, i.e., $(\tilde{X}_t, \tilde{V}_t)$ is uniformly distributed on $\mathcal{D} \times \mathbb{S}^{d-1}$. Then,*

$$(\tilde{X}_t, \tilde{V}_t)_{t\in\mathbb{R}} \stackrel{law}{=} (\tilde{X}_{-t}, -\tilde{V}_{-t})_{t\in\mathbb{R}}. \tag{13}$$

This relation shows that KSB with uniform initial condition is not only stationary, but also reversible up to a sign change in the speed. Also, it yields a pathwise construction of the stationary version of the KSB for all $t \in \mathbb{R}$ in the following way: first, choose a random point $(x_0, v_0) \in \bar{\mathcal{D}} \times \mathbb{S}^{d-1}$ according to the measure $\mu_0 \otimes \nu_0$. Construct a KSB $(\tilde{X}_t^{(1)}, \tilde{V}_t^{(1)})$ with the initial condition $(\tilde{X}_0^{(1)}, \tilde{V}_0^{(1)}) = (x_0, v_0)$, and an independent KSB $(\tilde{X}_t^{(2)}, \tilde{V}_t^{(2)})$ with the initial condition $(\tilde{X}_0^{(2)}, \tilde{V}_0^{(2)}) = (x_0, -v_0)$. Then, the process $(\tilde{X}_t, \tilde{V}_t)_{t\in\mathbb{R}}$ defined by

$$(\tilde{X}_t, \tilde{V}_t) = \begin{cases} (\tilde{X}_t^{(1)}, \tilde{V}_t^{(1)}) & \text{for } t \geq 0 \\ \\ (\tilde{X}_{-t}^{(2)}, -\tilde{V}_{-t}^{(2)}) & \text{for } t \leq 0 \end{cases}$$

is a stationary KSB.

For any measurable $A \subset \mathcal{D}$, define

$$\mathfrak{m}(A) = \mathbf{E}_{\hat{\mu}_0} \int_0^{\tau_1} \mathbf{1}\{\tilde{\xi}_0 + t\ell_{\tilde{\xi}_0, \tilde{\xi}_1} \in A\}\, dt$$

so $\mathfrak{m}(A)$ is the mean time that KSB starting from $\tilde{\xi}_0$ which is placed uniformly at random on $\partial\mathcal{D}$, spends in A till the next hit of the boundary. In particular,

$\bar{\mathfrak{m}} := \mathfrak{m}(\mathcal{D})$ is the mean time interval between the consecutive hittings of the boundary. Use the abbreviation

$$\kappa_d := \gamma_d |\mathbb{S}^{d-1}| = \frac{\pi^{1/2}\Gamma(\frac{d+1}{2})d}{\Gamma(\frac{d}{2}+1)}$$

(for instance, $\kappa_2 = \pi$, $\kappa_3 = 4$). Next, we calculate explicitly the quantity $\mathfrak{m}(A)$ (for the case of convex smooth domain, this formula can be obtained using the results of [4]).

Theorem 2.6 *Suppose that* $\operatorname{diam}(\mathcal{D}) < \infty$. *We have*

$$\mathfrak{m}(A) = \kappa_d \frac{|A|}{|\partial\mathcal{D}|}. \tag{14}$$

In particular, $\bar{\mathfrak{m}} = \kappa_d \frac{|\mathcal{D}|}{|\partial\mathcal{D}|}$.

The quantity $\bar{\mathfrak{m}}$ can be interpreted as "the mean chord length" for the domain $\mathcal{D}$, when the random chord constructed as follows: take a point on $\partial\mathcal{D}$ uniformly at random, and draw a line from there using the cosine probability distribution. Formally:

Definition 2.1 *The random chord for a bounded domain* $\mathcal{D}$ *satisfying our standing assumptions of Section 2.1, is a pair of random variables* (Ξ_1, Ξ_2), *in* $\partial\mathcal{D}$, *with the joint density* $|\partial\mathcal{D}|^{-1}\tilde{K}(x,y)$.

Note that, by symmetry of the above density, the construction defines an unoriented chord, as one expects from a random chord.

Remark. Here is another construction of the random chord, which is equivalent to Definition 2.1: pick some (x,v) in $\mathcal{D}\times\mathbb{S}^{d-1}$ according to the density $\frac{C}{\|\mathsf{h}_x(v)-\mathsf{h}_x(-v)\|}dx\,dv$ (C is the suitable normalizing constant), and put $\Xi_1 := \mathsf{h}_x(v)$, $\Xi_2 := \mathsf{h}_x(-v)$. This is so because the KSB beginning with a uniform distribution on $\partial\mathcal{D}$ is a Palm version of the stationary KSB, and therefore the above fact follows from Theorem 4.1 of Chapter 8 of [28] and Theorem 2.4. □

With this definition, the quantity $\bar{\mathfrak{m}} = \mathbf{E}\|\Xi_1 - \Xi_2\|$ is the mean chord length, and Theorem 2.6 has a nice geometric interpretation: the area (volume, ...) of the domain is always proportional to the product of its perimeter (surface area, ...) and $\bar{\mathfrak{m}}$:

$$|\mathcal{D}| = \frac{\bar{\mathfrak{m}}|\partial\mathcal{D}|}{\kappa_d}. \tag{15}$$

This result also shows that one can obtain the quantity $\frac{|\mathcal{D}|}{|\partial\mathcal{D}|}$ directly (i.e., without obtaining separately $|\mathcal{D}|$ and $|\partial\mathcal{D}|$) by simulating the KRW $\tilde{\xi}_n$.

Let us discuss some further properties of the above definition of random chord. The term "random chord" should remind the reader of the so-called Bertrand Paradox (see, for example, [16]), which can be briefly described as follows. A chord is chosen at random in a circle. The question is, what is the probability that the chord is longer than a side of the equilateral triangle inscribed in this circle? To answer this question, one considers three natural methods for choosing a chord at random.

1. The "random endpoints" method: choose two points independently uniformly on the circumference and draw the chord joining these two points. Note that this is equivalent to choosing a uniform point on the circumference and drawing a chord from there with the angle (between the chord and the radius) chosen uniformly at random in $(-\pi/2, \pi/2)$.

2. The "random radius" method: choose uniformly a radius of the circle and a point on the radius and construct the chord whose midpoint is the chosen point. It is easily verified that this is equivalent to choosing a uniform point on the circumference and drawing a chord from there according to the cosine distribution, so this method is equivalent to our method of choosing a random chord on a circle.

3. The "random midpoint" method: choose a point uniformly at random within the circle and construct a chord with the chosen point as its midpoint.

By elementary computations, one finds that the above probability is equal to 1/3, 1/2, 1/4 if the random chord is drawn from methods 1,2 and 3 respectively. It is then routinely argued, that the problem is not well formulated, since it is not clear which of the methods should be preferred, and the term "random chord" itself is not well defined. However, E. Jaynes [16] suggested that, among the three above methods, the method 2 is the "right" one, since it has certain invariance properties. (Recall that the method 2 is equivalent to our definition of random chord for the particular case of a circle.) In the next theorem we show that the random chord in the sense of Definition 2.1 also has similar properties, thus leading us to suggest that perhaps Definition 2.1 is the "right" definition of a random chord for general domains.

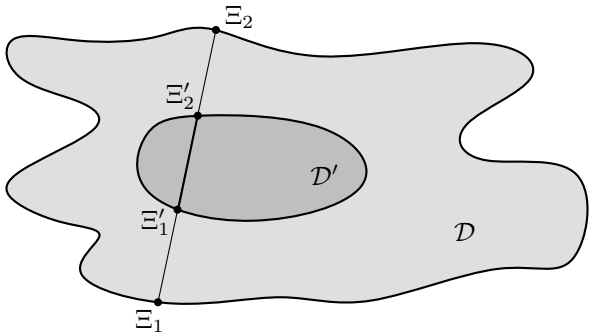

Figure 5: A random chord on $\mathcal{D}'$ induced by a random chord on $\mathcal{D}$

If $\mathcal{D}' \subset \mathcal{D}$ is convex, a chord of $\mathcal{D}$ which intersects $\mathcal{D}'$ defines a unique chord on $\mathcal{D}'$ by its intersection (see Figure 5). Let us generate independent random chords $(\Xi_1(i), \Xi_2(i))$ of $\mathcal{D}$, $i = 1, 2, \ldots$, till the chord hits the domain $\mathcal{D}'$, and then denote by (Ξ_1', Ξ_2') the intersection. We call (Ξ_1', Ξ_2') the *induced* chord on $\mathcal{D}'$. Like in the "acceptance-rejection" algorithm (or "hit or miss") for random variable simulation, we easily check that (Ξ_1', Ξ_2') has the same law as the endpoints of $[\Xi_1, \Xi_2] \cap \mathcal{D}'$ given that these sets intersect.

Theorem 2.7 *Let $\mathcal{D}' \subset \mathcal{D}$ be convex. Then, the chord induced on $\mathcal{D}'$ by the random chord of $\mathcal{D}$ is the random chord of $\mathcal{D}'$ in the sense of Definition 2.1.*

When the domain $\mathcal{D}'$ is not convex, the situation is more complicated, since a chord of $\mathcal{D}$ can intersect $\mathcal{D}'$ in several places. Denote by

$$(\Xi_{1,k}', \Xi_{2,k}') \,, \quad k \leq \iota$$

the chords obtained by intersecting $\mathcal{D}'$ with the chord (Ξ_1, Ξ_2) of $\mathcal{D}$, with $\iota \in \{0, 1, \ldots, \infty\}$ their number.

Theorem 2.8 *Let $\mathcal{D}' \subset \mathcal{D}$ be with the Lipschitz condition and an almost everywhere continuously differentiable boundary. For every Borel subset C of $\partial\mathcal{D}' \times \partial\mathcal{D}'$, we have*

$$\mathbf{E}\Big[\sum_{k=1}^{\iota} \mathbf{1}\{(\Xi_{1,k}', \Xi_{2,k}') \in C\}\Big] = \frac{|\partial\mathcal{D}'|}{|\partial\mathcal{D}|} \times |\partial\mathcal{D}'|^{-1} \int_C \tilde{K}(x, y) dx\, dy. \tag{16}$$

In particular,

$$\mathbf{E}[\iota] = \frac{|\partial\mathcal{D}'|}{|\partial\mathcal{D}|}. \tag{17}$$

Hence, the relation (16) has the following interpretation: the expected value of the measure giving unit weight to each chord induced on $\mathcal{D}'$ by the $\mathcal{D}$-random chord, is the product of the expected number of induced chords and the probability distribution for the (ordered) endpoints of the random chord of $\mathcal{D}'$. Another comment on this theorem is that the number ι of induced chords is integrable, a property which does not seem easy to prove directly. The formula (17) could remind the reader of the following fact concerning the so-called Poisson line process (see e.g. Section 8.4.2 of [27]): if $\mathcal{D}$ is compact and convex, then the number of lines hitting $\mathcal{D}$ has Poisson distribution with the mean proportional to the perimeter of $\mathcal{D}$.

Finally, we are interested in what happens at the moments when the KSB crosses a surface $S \subset \mathcal{D}$. Suppose that S is a compact (but not necessarily connected) $(d-1)$-dimensional manifold (possibly with boundary). Similarly to what we did for $\partial\mathcal{D}$, we assume also that S is locally Lipschitz and almost everywhere continuously differentiable. So, for a.a. $x \in S$ we can define a normal vector $\mathbf{n}(x)$ –this time there are two possible choices– and consider a family of rotations $(U_x, x \in S)$ with the property $U_x e = \mathbf{n}(x)$. We can make our construction so that the maps $x \mapsto \mathbf{n}(x)$ and $x \mapsto U_x$ are continuous a.e. in S.

Now consider the random surface crossing times $\hat{\tau}_n$ of the KSB. We define this sequence of random variables $\hat{\tau}_n$, $n = 1, 2, 3, \ldots$ in the following way:

$$\hat{\tau}_1 = \inf\{t \geq 0 : \tilde{X}_t \in S\},$$

and for $n \geq 1$

$$\hat{\tau}_{n+1} = \inf\{t > \hat{\tau}_n : \tilde{X}_t \in S\}.$$

It is not difficult to prove that for almost all the initial conditions (as well as e.g. when the starting location and direction are chosen independently and uniformly) the surface is intersected only finitely many times during any finite time interval: $\hat{\tau}_n \to +\infty$ as $n \to \infty$[1].

Define

$$w_n = \begin{cases} U^{-1}_{\tilde{X}_{\hat{\tau}_n}} \tilde{V}_{\hat{\tau}_n}, & \text{if } \tilde{V}_{\hat{\tau}_n} \cdot \mathbf{n}(\tilde{X}_{\hat{\tau}_n}) \geq 0, \\ -U^{-1}_{\tilde{X}_{\hat{\tau}_n}} \tilde{V}_{\hat{\tau}_n}, & \text{if } \tilde{V}_{\hat{\tau}_n} \cdot \mathbf{n}(\tilde{X}_{\hat{\tau}_n}) < 0, \end{cases}$$

[1] Indeed, first, analogously to Lemma 3.2, one can prove that a.s. all the points of crossing are regular points for S. Then, suppose that for some n the set $\{\xi_n + s(\xi_{n+1} - \xi_n), s \in [0,1]\} \cap S$ consists of infinitely many points. In this case, let $y_0 \in S$ be an accumulation point of this set; it is clear that $\ell_{\xi_n,\xi_{n+1}} \cdot \mathbf{n}(y_0) = 0$. But then, as in the end of the proof of part (i) of Lemma 3.2, one can prove that this happens with probability 0.

i.e., w_n is the relative direction in which the KSB crosses S for the nth time.

By Theorems 2.2 and 2.4 we know that $\tilde{V}_t$ has asymptotically uniform (and independent of the location) distribution, so, if one observes the process when it is inside some set $A \subset \mathcal{D}$ with *positive* Lebesgue measure, the empirical distribution of the direction should be asymptotically uniform as well. The next result shows that the situation is different when one considers the instances of intersection with a $(d-1)$-dimensional surface: in this case the law of intersection is actually the same as the law of reflection (this result is also connected to Theorem 2.8).

Theorem 2.9 *For a.a. initial conditions and any measurable $B \subset \mathbb{S}_e$ we have*

$$\lim_{n\to\infty} \frac{1}{n} \sum_{i=1}^{n} \mathbf{1}\{w_i \in B\} = \int_B \gamma_d \cos\varphi(e,u)\, du. \tag{18}$$

Remarks.

- From the proof of Theorem 2.9 it can be seen that a stronger result holds: if we keep track also on the location of crossings, then in the long time limit, the location is uniformly distributed and is independent of the direction.
- Even if one starts the KSB from the stationary measure, it is generally *not* true that $(w_n, n \geq 1)$ are identically distributed, and, in particular, it is not true that w_1 has the cosine law. Rather than constructing a counterexample formally, we refer the reader to Figure 6: it is easy to convince oneself that the law of w_1 should be close to uniform (and not cosine); more precisely, it converges to the uniform distribution as the number of vertical components of S converges to ∞.

3 Some auxiliary results and proof of the existence of the stochastic billiard process

First, we recall the definition of the α-dimensional Hausdorff measure. For any Borel set $A \subset \mathbb{R}^d$, define

$$\mathcal{H}^{\alpha}_{\delta}(A) = \inf\Big\{\omega_\alpha \sum_{j=1}^{\infty} \Big(\frac{\mathrm{diam}(B_j)}{2}\Big)^{\alpha}\Big\},$$

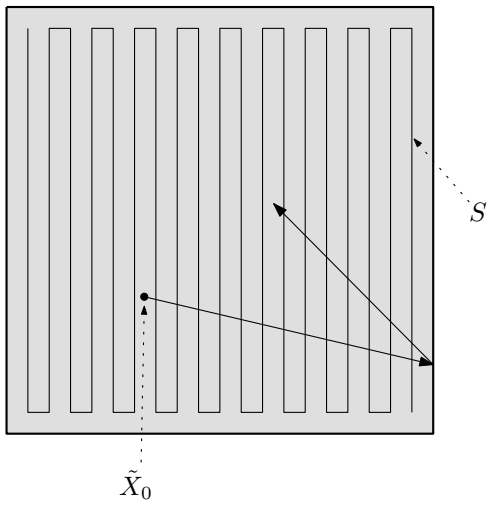

Figure 6: With high probability, the (relative) direction of the first crossing of S is equal to the initial direction

where $\omega_\alpha = \pi^{\alpha/2}/\Gamma(\alpha/2+1)$, and the infimum is taken over all collections of open sets $(B_j, j \geq 1)$ such that $\mathrm{diam}(B_j) \leq \delta$ for all j and $A \subset \bigcup_{j=1}^{\infty} B_j$. Then,

$$\mathcal{H}^\alpha(A) = \lim_{\delta \downarrow 0} \mathcal{H}^\alpha_\delta(A)$$

defines the α-dimensional Hausdorff measure of the set A.

We need to establish some properties of the domain $\mathcal{D}$.

Lemma 3.1 *Suppose that* $\mathrm{diam}(\mathcal{D}) < \infty$. *Then we have* $|\partial\mathcal{D}| < \infty$ *and the number of connected components of* $\partial\mathcal{D}$ *is finite.*

Proof. Let us show first that the area of a bounded surface satisfying the Lipschitz condition is finite. There is a deep theory related to Lipschitz functions and Hausdorff measure that can be found in e.g. [12, 23]; nevertheless, since we only need this simple fact, we sketch its proof here. Consider the following elementary observation: if a function f satisfies the Lipschitz condition with the constant C then, for any bounded $A \subset \mathbb{Z}^{d-1}$,

$$\begin{aligned}\mathrm{diam}\{z \in \mathbb{Z}^d : (z^{(1)}, \ldots, z^{(d-1)}) \in A, z^{(d)} = f(z^{(1)}, \ldots, z^{(d-1)})\} \\ \leq \ (C+1)^{1/2}\mathrm{diam}(A).\end{aligned}$$

From the above definition of the Hausdorff measure it is elementary to obtain that the area of $\partial\mathcal{D}$ is locally finite; since $\partial\mathcal{D}$ is compact, our claim follows.

Let us prove that the number of connected components of $\partial\mathcal{D}$ is finite. Suppose it is not the case; then enumerate these components in some way and choose any point x_j from jth connected component, $j = 1, 2, 3, \ldots$. Since $\mathcal{D}$ is bounded, there exists $x \in \bar{\mathcal{D}}$ such that x is an accumulation point of the sequence $(x_i, i \geq 1)$. Since $x_j \in \partial\mathcal{D}$ and $\partial\mathcal{D}$ is a closed set, we have $x \in \partial\mathcal{D}$. But then, in any arbitrarily small neighborhood of x one can find pieces of connected components different from that of x. This contradicts the Lipschitz condition, since we supposed that in $\mathcal{B}(x, \varepsilon_x)$ there are no other connected components of $\partial\mathcal{D}$. $\square$

For any $u \in \mathbb{S}^{d-1}$, $a, b > 0$, define

$$\mathfrak{C}_u(a, b) = \Big\{x \in \mathbb{R}^d \setminus \{0\} : \|x\| < a, \tan\varphi(u, x/\|x\|) < b\Big\},$$

so $\mathfrak{C}_u(a, b)$ is a piece of a cone, looking in the direction u.

The next lemma is a technical result that is needed, in particular, to show that the random variable ξ is a.s. well-defined for all n.

Lemma 3.2 *Suppose that* $\mathrm{diam}(\mathcal{D}) < \infty$.

(i) Consider any $x_0 \in \bar{\mathcal{D}}$ and let B be a subset of positive measure of $\mathbb{S}^{d-1}$ such that, for some $\varepsilon_0 > 0$, we have $x_0 + ut \in \mathcal{D}$ for all $u \in B$, $t \in (0, \varepsilon_0)$. Let ζ be a B-valued random variable with the distribution which is absolutely continuous with respect to the Haar measure on $\mathbb{S}^{d-1}$. Then, the distribution of $\mathsf{h}_{x_0}(\zeta)$ is absolutely continuous with respect to the $(d-1)$-dimensional Hausdorff measure on $\partial\mathcal{D}$. Moreover, with probability 1, $\varphi_{\mathsf{h}_{x_0}(\zeta)}(\ell_{\mathsf{h}_{x_0}(\zeta), x_0}) < \pi/2$.

(ii) The conditional distribution of ξ_{n+1} given $\xi_n = x_1 \in \mathcal{R}$, is absolutely continuous with respect to the $(d-1)$-dimensional Hausdorff measure on $\partial\mathcal{D}$.

Proof. First, we prove the part (i). We have to prove that the measure $\tilde{\mu}(A) = \mathbf{P}[\mathsf{h}_{x_0}(\zeta) \in A]$ is absolutely continuous with respect to the $(d-1)$-dimensional Hausdorff measure on $\partial\mathcal{D}$. Consider any $A \subset \partial\mathcal{D}$ such that $|A| = 0$. This means that, for any $\varepsilon > 0$, there are sequences $(z_i \in \mathbb{R}^d, i \geq 1)$ and $(r_i > 0, i \geq 1)$ such that

$$A \subset \bigcup_{i=1}^{\infty} \mathcal{B}(z_i, r_i) \quad \text{and} \quad \sum_{i=1}^{\infty} r_i^{d-1} < \varepsilon.$$

Without restricting the generality, one can suppose that the distance from x_0 to any of $\mathcal{B}(z_i, r_i)$ is at least $\varepsilon_0/2$. Let

$$B_i = \{u \in \mathbb{S}^{d-1} : \text{ there exists } t > 0 \text{ such that } x_0 + ut \in \mathcal{B}(z_i, r_i)\}$$

be the projection of $\mathcal{B}(z_i, r_i) - x_0$ on $\mathbb{S}^{d-1}$. Clearly, there exists $C_{\varepsilon_0} > 0$ such that $|B_i| \le C_{\varepsilon_0} r_i^{d-1}$. If $g(u)$ is the density of ζ, we can write

$$\mathbf{P}[\mathsf{h}_{x_0}(\zeta) \in A] \le \int_{\cup_{i=1}^{\infty} B_i} g(u)\, du;$$

on the other hand,

$$\Big|\bigcup_{i=1}^{\infty} B_i\Big| \le \sum_{i=1}^{\infty} |B_i| \le C_{\varepsilon_0} \sum_{i=1}^{\infty} r_i^{d-1} < \varepsilon C_{\varepsilon_0}.$$

Since ε is arbitrary, by the continuity property of the Lebesgue integral we obtain that $\tilde{\mu}(A) = 0$.

To complete the proof of part (i), observe that, with $\hat{\gamma}$ the density of ζ,

$$\begin{aligned}
\mathbf{P}[\mathsf{h}_{x_0}(\zeta) \in A] &= \int_{\mathbb{S}^{d-1}} \hat{\gamma}(v) \mathbf{1}\{\mathsf{h}_{x_0}(v) \in A\}\, dv \\
&= \int_{\mathbb{S}^{d-1}} \hat{\gamma}(v) \mathbf{1}\{\mathsf{h}_{x_0}(v) \in A \cap \mathcal{R}\}\, dv \\
&= \int_A \hat{\gamma}(\ell_{x_0,y}) \frac{\cos \varphi_y(\ell_{y,x_0})}{\|x_0 - y\|^{d-1}} \mathbf{1}\{y \in \mathcal{R}, x_0 \leftrightarrow y\}\, dy.
\end{aligned}$$

The second line is from the above absolute continuity, and the last line is obtained by the change of variables from $v \in \mathbb{S}^{d-1}$ to $y = \mathsf{h}_{x_0}(v) \in \partial\mathcal{D}$, which can be performed at regular points of the boundary provided that $\varphi_y(\ell_{y,x_0}) < \pi/2$.

Finally, it is an easy exercise to deduce the part (ii) from the part (i) (decompose $\mathbb{S}_{\mathbf{n}(x_1)}$ into the union of $D_j := \{u \in \mathbb{S}_{\mathbf{n}(x_1)} : \mathsf{r}_{x_1}(u) \in [1/(j+1), 1/j)\}$, $j \ge 1$, and $D_0 := \{u \in \mathbb{S}_{\mathbf{n}(x_1)} : \mathsf{r}_{x_1}(u) \ge 1\}$, and then use the part (i)). □

Define, for all $x \in \partial\mathcal{D}$,

$$\tilde{\alpha}_x = \sup\{s > 0 : \text{ there exists } u \in \mathbb{S}^{d-1} \text{ such that } x + \mathfrak{C}_u(s, s) \subset \mathcal{D}\}. \quad (19)$$

Let us prove that, under the Lipschitz condition formulated in Section 2.1, the domain $\mathcal{D}$ has the following properties:

Lemma 3.3 *(i) For any compact $A \subset \mathbb{R}^d$ there exists a constant $q(A) > 0$ such that $\tilde{\alpha}_x \geq q(A)$ for all $x \in \partial\mathcal{D} \cap A$.*

(ii) Suppose that $\operatorname{diam}(\mathcal{D}) < \infty$. Then, for any $x \in \partial\mathcal{D}$, there exist $\varepsilon, \varepsilon', \delta > 0$ and $y_x \in \mathcal{R}$ such that $K(y,z) > \delta$ for all $z \in \mathcal{B}(x,\varepsilon) \cap \mathcal{R}$, $y \in \mathcal{B}(y_x, \varepsilon')$.

(iii) Suppose that $x, y \in \mathcal{R}$ are such that $K(x,y) > 0$. Then there exist $\varepsilon, \varepsilon', \delta > 0$ such that $K(x',y') > \delta$ for all $x' \in \mathcal{B}(x,\varepsilon)$, $y' \in \mathcal{B}(y,\varepsilon')$.

Proof. Consider an arbitrary $x \in \partial\mathcal{D}$ and fix $a_0 < 1$ in such a way that $a_0(1-a_0^2)^{-1/2} < (2L_x)^{-1}$ (recall that we assumed $L_x > 1$). From the Lipschitz condition we obtain that for any $y \in \partial\mathcal{D} \cap \mathcal{B}(x, a_0\varepsilon_x)$ it holds that $y + \mathfrak{C}_{\mathfrak{I}_x^{-1}(e_d)}((1-a_0)\varepsilon_x, L_x^{-1}) \subset (\mathcal{D} \cap \mathcal{B}(x,\varepsilon_x))$. The collection $(\partial\mathcal{D} \cap \mathcal{B}(x, a_0\varepsilon_x), x \in \partial\mathcal{D} \cap A)$ is a covering of $\partial\mathcal{D} \cap A$; choose a finite subcovering to establish the property (i).

Let us prove the property (ii). Suppose that $\operatorname{diam}(\mathcal{D}) < \infty$ and observe that one can obtain (see Figure 7)

$$\mathcal{D} \cap \mathcal{B}(x,\varepsilon_x) \cap \bigcap_{y \in \partial\mathcal{D} \cap \mathcal{B}(x, a_0\varepsilon_x)} (y + \mathfrak{C}_{\mathfrak{I}_x^{-1}(e_d)}(\infty, (2L_x)^{-1})) \neq \emptyset.$$

This set being open, this implies that $|B_x| > 0$ (here $|\cdot|$ stands for the $(d-1)$-dimensional Hausdorff measure), where

$$B_x = \{z : \|z - x\| = \varepsilon_x\} \cap \bigcap_{y \in \partial\mathcal{D} \cap \mathcal{B}(x, a_0\varepsilon_x)} (y + \mathfrak{C}_{\mathfrak{I}_x^{-1}(e_d)}(\infty, (2L_x)^{-1})).$$

Note that any point of B_x is seen from any point of $\partial\mathcal{D} \cap \mathcal{B}(x, a_0\varepsilon_x)$, and for all $y \in B_x$ it holds that

$$\varphi_x(\ell_{x,y}) \geq \arctan L_x^{-1} - \arctan(2L_x)^{-1}. \tag{20}$$

Moreover, from Lemma 3.2 (i) it follows that one can find a point $y_x \in \mathcal{R}$ such that $\varepsilon_x \ell_{x,y_x} \in B_x$, $\varphi_{y_x}(\ell_{y_x,x}) < \pi/2$, and $x \leftrightarrow y_x$.

For $b_1, b_2 > 0$ denote

$$G_{b_1,b_2} = \{z \in \mathbb{R}^d : (z - y_x - b_1\ell_{y_x,x}) \cdot \ell_{y_x,x} = 0, \|z - y_x - b_1\ell_{y_x,x}\| < b_0\}.$$

Since $y_x \in \mathcal{R}$ and $\varphi_{y_x}(\ell_{y_x,x}) < \pi/2$, one can choose positive and small enough b_1, b_2, ε' (also with the property $b_1 < \|x - y_x\| - \varepsilon_x$) such that

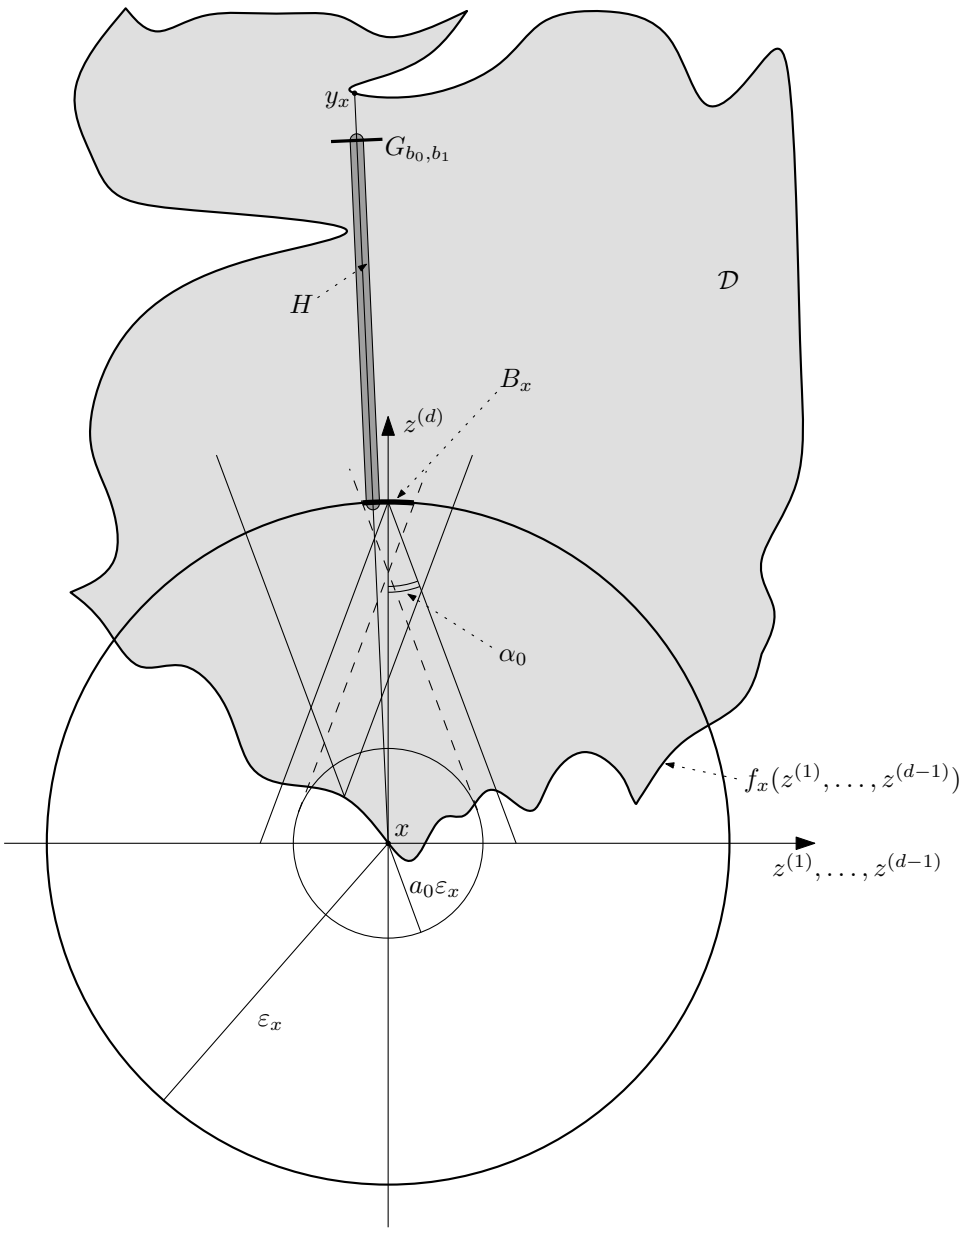

Figure 7: On the proof of Lemma 3.3 (ii), $\alpha_0 := \arctan(2L_x)^{-1}$

- $G_{b_1,b_2} \subset \mathcal{D}$;
- $\partial\mathcal{D} \cap \mathcal{B}(y_x, \varepsilon') \subset \mathcal{R}$;
- $y \leftrightarrow z$ for all $z \in G_{b_1,b_2}$, $y \in \partial\mathcal{D} \cap \mathcal{B}(y_x, \varepsilon')$.

Clearly, there is a small enough $b_2 \le b_0$ such that for the set

$$H = \{z : \text{ there exists } t \in [b_1, \|x - y_x\| - \varepsilon_x] \text{ such that } \|z - t\ell_{y_x,x}\| \le b_2\}$$

it holds that $H \subset \mathcal{D}$ and $\{z \in H : \|x - z\| = \varepsilon_x\} \subset B_x$. Then, one can find positive and small enough $s, \varepsilon_1' \le \varepsilon', a_1 \le a_0$ such that for any $y \in \partial\mathcal{D} \cap \mathcal{B}(y_x, \varepsilon_1')$

- $(y + \mathfrak{C}_{\ell_{y_x,x}}(\infty, s)) \cap \{z : \|z - x\| = \varepsilon_x\} \subset B_x$;
- $(y + \mathfrak{C}_{\ell_{y_x,x}}(\infty, s)) \cap \{z : (z - y_x - b_1\ell_{y_x,x}) \cdot \ell_{y_x,x}\} \subset G_{b_0,b_1}$;
- $\mathcal{B}(x, a_1\varepsilon_x) \subset (y + \mathfrak{C}_{\ell_{y_x,x}}(\infty, s))$.

Then, by construction, we obtain that $x' \leftrightarrow y$ for any $x' \in \partial\mathcal{D} \cap \mathcal{B}(x, a_1\varepsilon_x)$, $y \in \partial\mathcal{D} \cap \mathcal{B}(y_x, \varepsilon_1')$. For part (ii) it remains only to prove that the above parameters can be chosen in such a way that $K(x', y)$ is uniformly positive for regular points from the neighborhoods of x and y_x. This can be obtained easily, using that $\varphi_{y_x}(\ell_{y_x,x}) < \pi/2$ and (20).

Proving part (iii) is very similar to the last part of the proof of part (ii), so we do not provide the details. □

Now, we are ready to prove that the stochastic billiard process X_t is well defined for all $t \ge 0$.

Proof of Proposition 2.1. Fix any $T > 0$ and let us prove that

$$\lim_{n\to\infty} \tau_n > T \qquad \text{a.s.} \tag{21}$$

Consider the compact set $A = \{x \in \mathbb{R}^d : \|x - x_0\| \le T\}$ (recall that $\xi_0 = x_0$); by Lemma 3.3 (i), we have that $\tilde{\alpha}_x \ge q(A) > 0$ for all $x \in \partial\mathcal{D} \cap A$, where $\tilde{\alpha}_x$ was defined in (19). Denote $B_u = \{v \in \mathbb{S}^{d-1} : \tan\varphi(u, v) < q(A)\}$. Then, from (1) it is elementary to obtain that

$$\mathbf{P}[\|\xi_{n+1} - \xi_n\| \ge \tilde{\alpha}_x \mid \xi_n = x] \ge \inf_{u : B_u \subset \mathbb{S}_e} \mathbf{P}[\eta \in B_u] > 0 \tag{22}$$

for any $x \in \partial\mathcal{D} \cap A$. This means that, as long as $\tau_n \le T$ (and, consequently, $\xi_n \in \partial\mathcal{D} \cap A$), there is a uniformly positive probability that $\tau_{n+1} - \tau_n = \|\xi_{n+1} - \xi_n\| \ge q(A)$. This proves (21), and, since T is arbitrary, Proposition 2.1 holds. □

4 Proofs for the random walk

Here we prove the results concerning the discrete-time random walk ξ_n.

Proof of Theorem 2.1. First, our goal is to prove that the Döblin condition holds: there exist n_0, $\hat{\varepsilon} > 0$ such that for all $x, y \in \mathcal{R}$

$$K^{n_0}(x, y) \geq \hat{\varepsilon}. \tag{23}$$

To prove (23), let us first suppose that x and y are in the same connected component of $\partial\mathcal{D}$. Now, from Lemma 3.3 it follows that for any $x \in \partial\mathcal{D}$ we can find $\varepsilon(x), \delta(x) > 0$, $s(x) \in \mathcal{R}$ such that

$$\inf_{\substack{y \in \mathcal{R} \cap \mathcal{B}(x, \varepsilon(x)), \\ z \in \mathcal{R} \cap \mathcal{B}(s(x), \delta(x))}} K(y, z) > 0. \tag{24}$$

Note that $(\partial\mathcal{D} \cap \mathcal{B}(z, \varepsilon(z)), z \in \partial\mathcal{D})$ is a covering of $\partial\mathcal{D}$, so let us choose a finite subcovering $(\partial\mathcal{D} \cap \mathcal{B}(x_i, \varepsilon(x_i)), i = 1, \ldots, N)$. Abbreviate $B_{i,j} := \partial\mathcal{D} \cap \mathcal{B}(x_i, \varepsilon(x_i)) \cap \mathcal{B}(x_j, \varepsilon(x_j))$, let

$$\begin{aligned}
\beta &= \min_{i=1,\ldots,N} \inf_{\substack{y \in \mathcal{R} \cap \mathcal{B}(x_i, \varepsilon(x_i)), \\ z \in \mathcal{R} \cap \mathcal{B}(s(x_i), \delta(x_i))}} K(y, z), \\
\theta_1 &= \min_{i,j : B_{i,j} \neq \emptyset} |B_{i,j}|, \\
\theta_2 &= \min_{i=1,\ldots,N} |\partial\mathcal{D} \cap \mathcal{B}(s(x_i), \delta(x_i))|
\end{aligned}$$

(note that all the quantities, defined above, are strictly positive).

Since x, y are from the same connected component, there exists $m \leq N$ and $k(1), \ldots, k(m) \in \{1, \ldots, N\}$, such that $x \in \mathcal{R} \cap \mathcal{B}(x_{k(1)})$, $y \in \mathcal{R} \cap \mathcal{B}(x_{k(m)})$, and $B_{k(i),k(i+1)} \neq \emptyset$ for all $i = 1, \ldots, m-1$. Note also that one can suppose that m is the same for all x, y (and even that it does not depend on the connected component of $\partial\mathcal{D}$ to which belong x and y), since we formally can choose $k(i) = k(i+1)$ in the above sequence. So, abbreviating $D_j = \mathcal{R} \cap \mathcal{B}(s(x_{k(j)}), \delta(x_{k(j)}))$, we can write

$$\begin{aligned}
K^{2m}(x, y) \;\geq\; & \int_{D_1} dz_1 \int_{B_{k(1),k(2)}} dw_1 \int_{D_2} dz_2 \\
& \ldots \int_{D_{m-1}} dz_{m-1} \int_{B_{k(m-1),k(m)}} dw_{m-1} \int_{D_m} dz_m
\end{aligned}$$

$$
\begin{aligned}
& K(x,z_1)K(z_1,w_1)K(w_1,z_2)\dots K(w_{m-2},z_{m-1}) \\
& \times K(z_{m-1},w_{m-1})K(w_{m-1},z_m)K(z_m,y) \\
\geq\ & \beta^{2m-1}\theta_1^{m-1}\theta_2^m,
\end{aligned}
$$

which proves (23) for the case when x, y are in the same connected component of $\partial\mathcal{D}$.

Now, we sketch the proof of (23) for the case when x, y are in different connected components of $\partial\mathcal{D}$; we leave the details to the reader. Suppose that there are M connected components of $\partial\mathcal{D}$, so that $\partial\mathcal{D} = \cup_{i=1}^M G_i$. Let $a_{ij} = 1$ if there exist $z_{ij} \in G_i \cap \mathcal{R}$, $z_{ji} \in G_j \cap \mathcal{R}$ such that $K(z_{ij}, z_{ji}) > 0$, and $a_{ij} = 0$ otherwise. In words, $A = (a_{ij})_{i,j=1\dots,M}$ is the matrix that describes the "graph" of the set of connected components of $\partial\mathcal{D}$. It is clear that the matrix A is irreducible, let us prove that it is aperiodic. Let G_{i_0} be the connected component of $\partial\mathcal{D}$ which is the boundary of the unique infinite connected component of $\mathbb{R}^d \setminus \mathcal{D}$, we show that $a_{i_0 i_0} = 1$. Let x_0 be an exposed point of the convex hull of $\bar{\mathcal{D}}$[2], and let H be a supporting hyperplane of the convex hull of $\bar{\mathcal{D}}$ at x_0, i.e., $H \cap \bar{\mathcal{D}} = \{x_0\}$. From the Lipschitz condition (see also the proof of Lemma 3.3 (i)) we know that for some $u \in \mathbb{S}^{d-1}, b_1, b_2 > 0$, it holds that $\mathfrak{C}_u(b_1, b_2) \subset \mathcal{D}$. Let (see Figure 8)

$$
H_t = \{tu + z : z \in H \text{ is such that } tu + \alpha z \in \mathcal{D} \text{ for all } \alpha \in [0,1)\}.
$$

Let

$$
\varepsilon_0 = \inf\{\|x - y\| : x \in H, y \in \partial\mathcal{D}, \|y - x_0\| = \varepsilon_x/2\} > 0.
$$

Clearly, H_t is a bounded set for all $t \in (0, \varepsilon_0)$ and $\overline{H_t} \cap \partial\mathcal{D}$ contains only the points of the connected component of x_0. Let ζ_1 be a random variable with uniform distribution on $(0, \varepsilon_0)$, and ζ_2 a random variable with uniform distribution on $\mathbb{S}^{d-1} \cap (H - x_0)$. Define $y_1 \in H_{\zeta_1}$ such that $y_1 = \zeta_1 u + \alpha_1 \zeta_2$ for some $\alpha_1 > 0$, and $y_2 \in H_{\zeta_1}$ such that $y_2 = \zeta_1 u - \alpha_2 \zeta_2$ for some $\alpha_2 > 0$. By construction, we have that y_1, y_2 are in the connected component of x_0 and $y_1 \leftrightarrow y_2$. Similarly to the proof of Lemma 3.2 (i), one can show that a.s. $y_1, y_2 \in \mathcal{R}$ and $\varphi(\mathbf{n}(y_1), \ell_{y_1,y_2}) \in [0, \pi/2)$, $\varphi(\mathbf{n}(y_2), \ell_{y_2,y_1}) \in [0, \pi/2)$.

Thus, there exists m_1 such that $A^{m_1} > 0$. Consider any $x \in G_i$, $y \in G_j$, there exist $i = k_0, k_1, \dots, k_{m_1-1}, k_{m_1} = j$ such that $a_{k_l k_{l+1}} = 1$ for $l = 0, \dots, m_1 - 1$. Then, roughly speaking, we go from x to $z_{k_0 k_1}$ in $2m$ steps,

[2] i.e., such that there exists an hyperplane H which intersects the convex hull of $\bar{\mathcal{D}}$ only at $\{x_0\}$

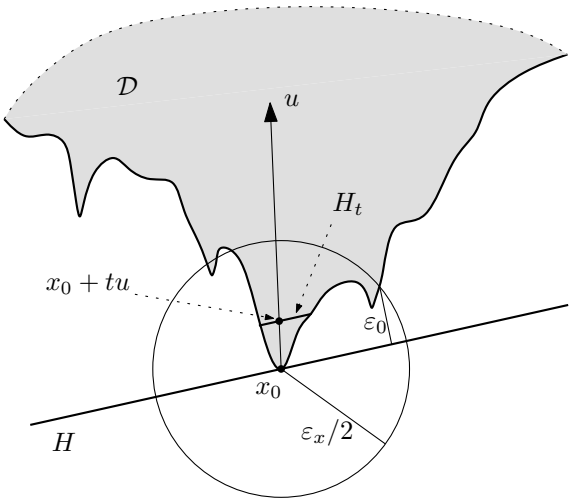

Figure 8: Finding two regular points which see each other

then (recall Lemma 3.3 (iii)) jump from $z_{k_0k_1}$ to $z_{k_1k_0}$, then go from $z_{k_1k_0}$ to $z_{k_1k_2}$ in $2m$ steps etc. This shows that (23) holds with $n_0 = 2m(m_1 + 1)$.

Now, having (23) at hand, it is straightforward to observe that there exists a coupling of two versions ξ and ξ' of the random walk with arbitrary starting conditions such that $\mathbf{P}[\xi_{n_0} = \xi'_{n_0}] \geq \bar{\varepsilon} := \hat{\varepsilon}|\partial\mathcal{D}|$. This in turn means that one can construct the two processes ξ and ξ' together with a random variable $\tilde{T}$ in such a way that $\xi_{\tilde{T}+k} = \xi'_{\tilde{T}+k}$ for all $k \geq 0$, and this random variable $\tilde{T}$ (which is the *exact coupling time* for the two processes) has the property

$$\mathbf{P}[\tilde{T} > kn_0] \leq (1 - \bar{\varepsilon})^k.$$

Applying Theorem 5.1 of Chapter 4 from [28], we obtain (6).

The absolute continuity of $\hat{\mu}$ with respect to the $(d-1)$-dimensional Hausdorff measure follows from Lemma 3.2 (ii), and the equation (5) follows from the fact that if the distribution of ξ_0 is $\hat{\mu}$, then so is the distribution of ξ_1. Note that $\psi(x) = \int_{\partial\mathcal{D}} \psi(y) K^{n_0}(y, x)\, dy$ for $x \in \mathcal{R}$, so from (23) it follows that $\inf_{\partial\mathcal{D}} \psi \geq \hat{\varepsilon}$.

We end by proving (7). This is now completely standard, a direct consequence of (ii)-(iv), Theorem 17.0.1 in [22]. □

5 Proofs for the continuous time stochastic billiard

In this section we prove the results concerning the continuous-time stochastic billiard.

Proof of Proposition 2.2. For $0 \le u \le t$, we have

$$\begin{aligned}
&\mathbf{E}\Big[f(X_t,V_t) - f(X_u,V_u) - \int_u^t \mathcal{L}f(X_s,V_s)ds \,\Big|\, \mathfrak{F}_u\Big] && (25)\\
&= \mathbf{E}\Big[\sum_{n\ge 0} \mathbf{1}\{u<\tau_n,\tau_{n-1}\le t\}\Big(f(X_{\tau_n\wedge t},V_{\tau_n\wedge t}) - f(X_{\tau_{n-1}\vee u},V_{\tau_{n-1}\vee u})\\
&\qquad\qquad - \int_{\tau_{n-1}\vee u}^{\tau_n\wedge t} \mathcal{L}f(X_s,V_s)ds\Big) \,\Big|\, \mathfrak{F}_u\Big]\\
&= \sum_{n\ge 0} \mathbf{E}\Big[\mathbf{1}\{u<\tau_n,\tau_{n-1}\le t\}\Big(f(X_{\tau_n\wedge t},V_{\tau_n\wedge t}) - f(X_{\tau_{n-1}\vee u},V_{\tau_{n-1}\vee u})\\
&\qquad\qquad - \int_{\tau_{n-1}\vee u}^{\tau_n\wedge t} \mathcal{L}f(X_s,V_s)ds\Big) \,\Big|\, \mathfrak{F}_u\Big] && (26)\\
&= \sum_{n\ge 0} \mathbf{E}\Big[\mathbf{1}\{u<\tau_n\le t\}\Big(f(X_{\tau_n},V_{\tau_n}) - f(X_{\tau_n},V_{\tau_{n-1}})\Big) \,\Big|\, \mathfrak{F}_u\Big] && (27)\\
&= 0, && (28)
\end{aligned}$$

where we have used Fubini's theorem in (26), the fundamental theorem of calculus in (27), and the boundary conditions (8) in (28). This proves that (9) defines a martingale. □

Proof of Theorem 2.2. To prove (10), we use the approach of [28]. By compactness of the state space $\mathcal{D}\times\mathbb{S}^{d-1}$, there exists at least one invariant probability measure χ for the Markov process (X_t,V_t). Consider the process (X_t,V_t) starting from an arbitrary initial position x_0 and initial direction v_0, and consider also the stationary version $(\hat{X}_t,\hat{V}_t)$ of this process (i.e., $(\hat{X}_0,\hat{V}_0)\sim\chi$, which implies that $(\hat{X}_t,\hat{V}_t)\sim\chi$ for all t). Our goal now is to construct an exact coupling of (X_t,V_t) and $(\hat{X}_t,\hat{V}_t)$, i.e., we construct these processes together with a random variable $\hat{T}$ (the coupling time) on a same probability space in such a way that

$$(X_{\hat{T}+s},V_{\hat{T}+s}) = (\hat{X}_{\hat{T}+s},\hat{V}_{\hat{T}+s})$$

for all $s \geq 0$. Also, we show that $\hat{T}$ has exponential tail, which in its turn ensures (10).

Definition 5.1 *We say that a pair of random variables (X, T), $X \in \partial\mathcal{D}, T \in \mathbb{R}_+$ is α-continuous on the set $A \times B$, $A \subset \partial\mathcal{D}, B \subset \mathbb{R}_+$, if for any measurable $A_1 \subset A$, $B_1 \subset B$*

$$\mathbf{P}[X \in A_1, T \in B_1] \geq \alpha |A_1||B_1|.$$

For any $x \in \partial\mathcal{D}$, $\varepsilon > 0$, define $\Delta_x^\varepsilon = \mathcal{B}(x, \varepsilon) \cap \mathcal{R}$. In the sequel, we will write ξ_n^a for the position of the random walk that started in a, τ_n^a for the corresponding local times. Note that, if we consider the pair (ξ_1^a, τ_1^a), its joint distribution is singular with respect to the Lebesgue measure (although typically the distribution of each component is absolutely continuous). The next lemma shows that in two steps the situation is already better.

Fix an arbitrary $x_1 \in \mathcal{R}$ with the following property: there exists $y_1 \in \mathcal{R}$ such that $K(x_1, y_1) > 0$ and $\mathbf{n}(y_1) \cdot \ell_{y_1, x_1} < 1$.

Lemma 5.1 *There exist $\alpha_1, \varepsilon > 0$, $\hat{r}_2 > \hat{r}_1 > 0$ such that, for any $x \in \Delta_{x_1}^\varepsilon$, the pair (ξ_2^x, τ_2^x) is α_1-continuous on $\Delta_{x_1}^\varepsilon \times (\hat{r}_1, \hat{r}_2)$.*

Proof. Choose small enough $\varepsilon, \varepsilon'$ in such a way that $K(x, y) > h_1$ for all $x \in \Delta_{x_1}^\varepsilon$, $y \in \Delta_{y_1}^{\varepsilon'}$ (this is possible by Lemma 3.2 (iii); note that $\Delta_{x_1}^\varepsilon \cup \Delta_{y_1}^{\varepsilon'} \subset \mathcal{R}$). Denote by

$$H = \{y' \in \mathbb{R}^d : \ (y' - y_1) \cdot \mathbf{n}(y_1) = 0\}$$

the tangent hyperplane at the point y_1, and let

$$v_1 = (\mathbf{n}(y_1) \cdot \ell_{y_1, x_1}) \mathbf{n}(y_1) - \ell_{y_1, x_1}.$$

Note that

- $v_1 + y_1 \in H$ (in fact, v_1 is the projection of the vector $\mathbf{n}(y_1) - \ell_{y_1, x_1}$ onto the hyperplane $H - y_1$);
- $v_1 \cdot \ell_{y_1, x_1} < 0$ (since $v_1 \cdot \ell_{y_1, x_1} = (\mathbf{n}(y_1) \cdot \ell_{y_1, x_1})^2 - 1$ is negative by the choice of y_1).

For notational convenience, for the rest of the proof we assume that $d \geq 3$; it is straightforward to adapt the proof for the case $d = 2$ (in fact, the proof in this case is much simpler, since the sets G, G_1, G_1^+, G_1^- defined below would be simply one point sets).

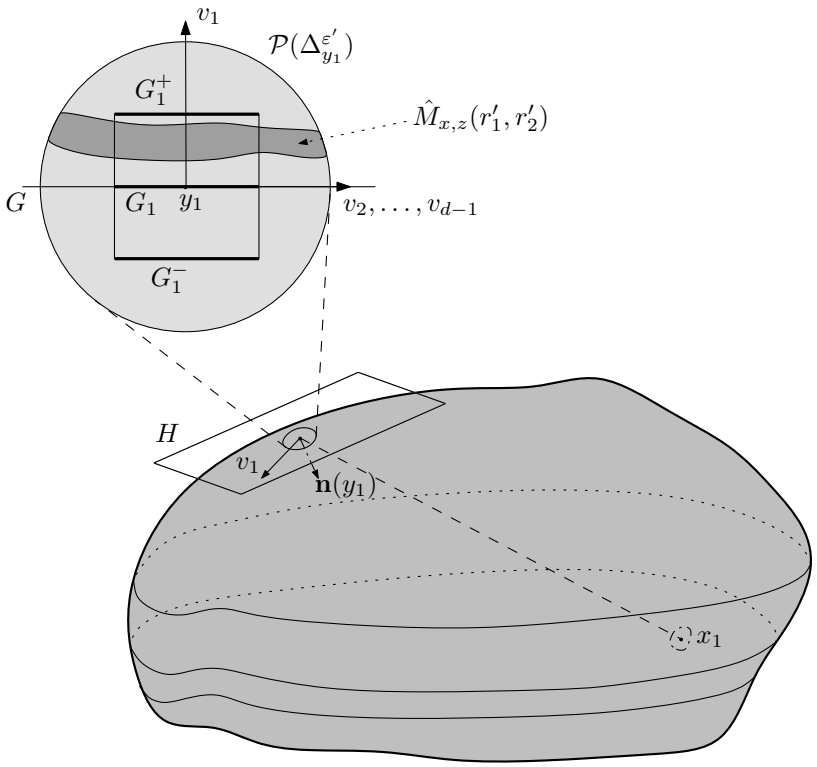

Figure 9: On the proof of Lemma 5.1

Consider the $(d-2)$-dimensional plane (see Figure 9)

$$G = \{z \in \mathbb{R}^d : \ (z - y_1) \cdot v_1 = 0\} \cap H.$$

One can easily see that if $y' - y_1 \in G$, then $(y' - y_1) \cdot \ell_{y_1,x_1} = 0$. Let us choose an orthonormal basis $v_2, \ldots, v_{d-1}$ in $G - y_1$, so that $v_1, v_2, \ldots, v_{d-1}$ is an orthonormal basis in $H - y_1$. Let $\mathcal{P} : \partial D \to H$ be the projection operator defined by

$$\mathcal{P}y = y - \big((y - y_1) \cdot \mathbf{n}(y_1)\big)\mathbf{n}(y_1),$$

and denote, with $R^x(y,z) := \|x - y\| + \|y - z\|$,

$$\theta_v(t) := R^{x_1}(\mathcal{P}^{-1}(y_1 + vt), x_1) = 2\|\mathcal{P}^{-1}(y_1 + vt) - x_1\|.$$

As $\mathcal{P}^{-1}(y_1 + vt) = y_1 + vt + O(t^2)$ when $t \to 0$, using also the fact that $\nabla\|x\| = \frac{x}{\|x\|}$, we have

$$\theta_v'(0) = \frac{2(y_1 + vt - x_1)}{\|y_1 + vt - x_1\|} \cdot v\Big|_{t=0} = 2\ell_{x_1,y_1} \cdot v \tag{29}$$

(note that $y_1 - x_1 = -\ell_{y_1,x_1}\|y_1 - x_1\|$).

Since $v_1, \ldots, v_{d-1}$ is a basis in $H - y_1$, any $s \in H - y_1$ can be uniquely represented as

$$s = s^{(1)}v_1 + \cdots + s^{(d-1)}v_{d-1},$$

so we regard $s^{(1)}, \ldots, s^{(d-1)}$ as the coordinates of s. Note that $\mathcal{P}^{-1}(s + y_1) \in \partial\mathcal{D}$ and let us consider the function

$$\Psi_{x,z}(s) = R^x(\mathcal{P}^{-1}(s + y_1), z).$$

From (29) we obtain (recall that G is perpendicular to ℓ_{x_1,y_1})

$$\begin{aligned} \frac{\partial\Psi_{x_1,x_1}(s)}{\partial s^{(1)}}\Big|_{s=0} &= 2\ell_{x_1,y_1} \cdot v_1 =: h > 0, \\ \frac{\partial\Psi_{x_1,x_1}(s)}{\partial s^{(i)}}\Big|_{s=0} &= 0, \quad \text{for } i = 2, \ldots, d-1. \end{aligned} \tag{30}$$

Since $\Psi_{x,z}(s)$ is continuously differentiable, for small enough $\varepsilon, \varepsilon'$ we obtain that for $x, z \in \Delta^{\varepsilon}_{x_1}$ and $s + y_1 \in \Delta^{\varepsilon'}_{y_1}$,

$$\frac{\partial\Psi_{x,z}(s)}{\partial s^{(1)}} \in \Big[\frac{3h}{4}, 2h\Big], \tag{31}$$

$$\frac{\partial \Psi_{x_1,x_1}(s)}{\partial s^{(i)}} \;\le\; \frac{h}{4}, \quad \text{for } i = 2, \dots, d-1. \tag{32}$$

Denote $G_1 = \{z \in G : \|z - y_1\| \le \varepsilon'/2\}$, $G_1^+ = G_1 + \frac{\varepsilon'}{2} v_1$, $G_1^- = G_1 - \frac{\varepsilon'}{2} v_1$ (again, see Figure 9). Clearly, if ε' is small enough,

$$\{s + t v_1 : s \in G_1, t \in [-\varepsilon'/2, \varepsilon'/2]\} + y_1 \subset \mathcal{P}(\Delta_{y_1}^{\varepsilon'}).$$

Let

$$\hat{r}_1 = \sup_{x,z \in \Delta_{x_1}^{\varepsilon}} \sup_{s \in G_1^-} \Psi_{x,z}(s), \quad \hat{r}_2 = \inf_{x,z \in \Delta_{x_1}^{\varepsilon}} \inf_{s \in G_1^+} \Psi_{x,z}(s).$$

Let us show that $\hat{r}_1 < \hat{r}_2$. Indeed,

$$\Psi_{x,z}\Big(\frac{\varepsilon'}{2} v_1\Big) - \Psi_{x,z}\Big(-\frac{\varepsilon'}{2} v_1\Big) \ge \frac{3h}{4}\varepsilon'$$

by (31), and for any $s \in G_1^+$

$$\Psi_{x,z}\Big(\frac{\varepsilon'}{2} v_1\Big) - \Psi_{x,z}(s) \le \frac{h}{4}\varepsilon'$$

by (32), and the similar inequality holds for any $s \in G_1^-$. So, we obtain that $\hat{r}_2 - \hat{r}_1 \ge \frac{3h}{4}\varepsilon' - \frac{h}{4}\varepsilon' - \frac{h}{4}\varepsilon' = \frac{h}{4}\varepsilon'$.

Let

$$\begin{aligned} M_{x,z}(r_1', r_2') &= \{y \in \Delta_{y_1}^{\varepsilon'} : R^x(y,z) \in (r_1', r_2')\}, \\ \hat{M}_{x,z}(r_1', r_2') &= \{s \in \mathcal{P}(\Delta_{y_1}^{\varepsilon'}) - y_1 : \ \Psi_{x,z}(s) \in (r_1', r_2')\}; \end{aligned}$$

observe that $M_{x,z}(r_1', r_2') = \mathcal{P}^{-1}(\hat{M}_{x,z}(r_1', r_2'))$.

Note the following simple fact: if for all $x \in [a_1, a_2]$ we have $c_1 < g'(x) < c_2$ where $0 < c_1 < c_2 < \infty$, then for any $I \subset [f(a_1), f(a_2)]$ it holds that $c_2^{-1}|I| \le |f^{-1}(I)| \le c_1^{-1}|I|$. Using this for $g_s(t) = \Psi_{x,z}(s + v_1 t)$ (recall that, by (31), $g'(t) \in [3h/4, 2h]$) we obtain

$$|\hat{M}_{x,z}(r_1', r_2')| \ge \int_{G_1} \big|g_s^{-1}\big((r_1', r_2')\big)\big|\, ds \ge |G_1|(2h)^{-1}(r_1' - r_2')$$

for all $(r_1', r_2') \subset (\hat{r}_1, \hat{r}_2)$. Clearly, for small enough ε', there exists a constant c' such that for any measurable $A \subset \mathcal{P}^{-1}(\Delta_{y_1}^{\varepsilon'})$ we have $|\mathcal{P}^{-1}(A)| \ge c'|A|$. This implies that there exists $\alpha' > 0$ such that for all $x, z \in \Delta_{x_1}^{\varepsilon}$

$$|M_{x,z}(r_1', r_2')| \ge \alpha'(r_2' - r_1'). \tag{33}$$

Now, for arbitrary $A_1 \subset \Delta^{\varepsilon}_{x_1}$, $(r_1', r_2') \subset (\hat{r}_1, \hat{r}_2)$, and $x \in \Delta^{\varepsilon}_{x_1}$, using (33) we can write

$$\begin{aligned}
&\mathbf{P}[\xi_2^x \in A_1, \tau_2^x \in (r_1', r_2')] \\
&\quad \geq \int_{\Delta^{\varepsilon'}_{y_1}} dy \int_{A_1} K(x,y)K(y,z)\mathbf{1}\{R^x(y,z) \in (r_1', r_2')\}\, dz \\
&\quad \geq h_1^2 \alpha' |A_1| (r_2' - r_1'),
\end{aligned}$$

so (ξ_2^x, τ_2^x) is α_1-continuous on $\Delta^{\varepsilon}_{x_1} \times (\hat{r}_1, \hat{r}_2)$ with $\alpha_1 = h_2^2 \alpha'$. Lemma 5.1 is proved. □

We continue the proof of Theorem 2.2. Fix any $b > 1$ such that

$$b^{-1}\hat{r}_2 - b\hat{r}_1 > \max\{(b-1)\hat{r}_1, (1-b^{-1})\hat{r}_2\}.$$

The following result is a logical continuation of Lemma 5.1.

Lemma 5.2 *For any $k \geq 1$ there exists $\alpha_k > 0$ such that for all $x \in \Delta^{\varepsilon}_{x_1}$, $(\xi_{2k}^x, \tau_{2k}^x)$ is α_k-continuous on $\Delta^{\varepsilon}_{x_1} \times (kb\hat{r}_1, kb^{-1}\hat{r}_2)$.*

Proof. We proceed by induction. The case $k = 1$ follows from Lemma 5.1. Let $k \geq 2$ and suppose that $(\xi_{2(k-1)}^x, \tau_{2(k-1)}^x)$ is α_{k-1}-continuous on $\Delta^{\varepsilon}_{x_1} \times ((k-1)b\hat{r}_1, (k-1)b\hat{r}_2)$. Using Lemma 5.1 and the induction assumption, write for any $A_1 \subset \Delta^{\varepsilon}_{x_1}$, $(r_1', r_2') \subset (kb\hat{r}_1, kb^{-1}\hat{r}_2)$

$$\begin{aligned}
&\mathbf{P}[\xi_{2k}^x \in A_1, \tau_{2k}^x \in (r_1', r_2')] \\
&\quad \geq \int_{\Delta^{\varepsilon}_{x_1}} \int_{(k-1)b\hat{r}_1}^{(k-1)b^{-1}\hat{r}_2} \mathbf{P}[\xi_{2(k-1)}^x \in dz, \tau_{2(k-1)}^x \in dt]\mathbf{P}[\xi_2^z \in A_1, \tau_2^z + t \in (r_1', r_2')] \\
&\quad \geq \int_{\Delta^{\varepsilon}_{x_1}} \int_{(k-1)b\hat{r}_1}^{(k-1)b^{-1}\hat{r}_2} \alpha_{k-1}\, dz\, dt \int_{A_1} \int_{(r_1'-t, r_2'-t)\cap(\hat{r}_1,\hat{r}_2)} \alpha_1 dz'\, dt' \\
&\quad \geq \hat{C}\alpha_{k-1}\alpha_1 |A_1| (r_2' - r_1'), \qquad (34)
\end{aligned}$$

where

$$\hat{C} = \frac{\min\{(b-1)\hat{r}_1, (1-b^{-1})\hat{r}_2\}}{\min\{\hat{r}_2 - \hat{r}_1, (k-1)(b^{-1}\hat{r}_2) - b\hat{r}_1\}}.$$

One can obtain the last inequality in (34) (together with the value of $\hat{C}$ given above) using the following fact: the convolution of functions $C_1\mathbf{1}\{x \in [0, a_1]\}$

and $C_2\mathbf{1}\{x \in [0, a_2]\}$ (where $a_1 \le a_2$) is a function supported on $[0, a_1 + a_2]$, which grows linearly from 0 to C_1C_2 on the interval $[0, a_1]$, then is flat on the interval $[a_1, a_2]$, then decreases linearly from C_1C_2 to 0 on the interval $[a_2, a_1 + a_2]$. So, if one considers any interval $[c, c']$ with $c > 0$ and $c' < a_1 + a_2$, then the convolution is uniformly positive (and one can easily calculate its minimum) on that interval. Note that in our case $c = (b-1)\hat{r}_1$, $a_1 + a_2 - c' = (1-b^{-1})\hat{r}_2$.

Lemma 5.2 now follows from (34). □

Now, let us choose k_0 in such a way that $k_0(b^{-1}\hat{r}_2 - b\hat{r}_1) > (n_0+1)\mathrm{diam}(\mathcal{D})$, where n_0 is from (23). Define

$$\begin{aligned} r_3 &= k_0 b\hat{r}_1 + n_0\mathrm{diam}(\mathcal{D}), \\ r_4 &= k_0 b^{-1}\hat{r}_2. \end{aligned}$$

It is important to observe that $r_4 - r_3 > \mathrm{diam}(\mathcal{D})$.

Lemma 5.3 *There exists $\hat{\alpha} > 0$ such that $(\xi^y_{n_0+2k_0}, \tau^y_{n_0+2k_0})$ is $\hat{\alpha}$-continuous on $\Delta^\varepsilon_{x_1} \times (r_3, r_4)$ for any $y \in \mathcal{R}$.*

Proof. Consider any $A_1 \subset \Delta^\varepsilon_{x_1}$ and $(r', r'') \subset (r_3, r_4)$. Let $\Phi^y_x(t)$ be the distribution of $\tau^y_{n_0}$ conditioned on $\{\xi^y_{n_0} = x\}$. Using (23) and Lemma 5.2 and the fact that the size of jumps of KRW cannot be larger than $\mathrm{diam}(\mathcal{D})$, write

$$\begin{aligned} &\mathbf{P}[\xi^y_{n_0+2k_0} \in A_1, \tau^y_{n_0+2k_0} \in (r', r'')] \\ &\quad\ge \int_{\Delta^\varepsilon_{x_1}} K^{n_0}(y, x)\, dx \int_0^{n_0\mathrm{diam}(\mathcal{D})} \mathbf{P}[\xi^x_{2k_0} \in A_1, \tau^x_{2k_0} \in (r' - t, r'' - t)]\, d\Phi^y_x(t) \\ &\quad\ge \hat{\varepsilon}|\Delta^\varepsilon_{x_1}|\alpha_{k_0}|A_1|(r'' - r'), \end{aligned}$$

so Lemma 5.3 holds with $\hat{\alpha} = \hat{\varepsilon}|\Delta^\varepsilon_{x_1}|\alpha_{k_0}$. □

Now, we are ready to construct a coupling of two versions of the stochastic billiard process with different starting conditions. Let (X_t, V_t) be the stochastic billiard with the initial condition $(X_0, V_0) = (x_0, v_0) \in \mathcal{D} \times \mathbb{S}^{d-1}$, and (X'_t, V'_t) has the initial condition $(X'_0, V'_0) = (x'_0, v'_0)$. Let

$$\tilde{\tau} = \inf\{t \ge 0 : x_0 + tv_0 \in \partial\mathcal{D}\}, \qquad w = x_0 + \tilde{\tau}v_0$$

be the time when (X_t, V_t) first hits the boundary, and the hitting location, and let

$$\tilde{\tau}' = \inf\{t \ge 0 : x'_0 + tv'_0 \in \partial\mathcal{D}\}, \qquad w' = x'_0 + \tilde{\tau}'v'_0$$

be the corresponding quantities for the process (X'_t, V'_t).

By Lemma 5.3, the pairs of random variables $(\xi^w_{n_0+2k_0}, \tilde{\tau} + \tau^w_{n_0+2k_0})$ and $(\xi^{w'}_{n_0+2k_0}, \tilde{\tau}' + \tau^{w'}_{n_0+2k_0})$ are both $\hat{\alpha}$-continuous on $\Delta^{\varepsilon}_{x_1} \times (r_3, r_4)$. Abbreviate $\hat{h} := r_4 - r_3 - \mathrm{diam}(\mathcal{D}) > 0$. Since $|\tilde{\tau} - \tilde{\tau}'| \le \mathrm{diam}(\mathcal{D})$, we obtain that

$$|(r_3 + \tilde{\tau}, r_4 + \tilde{\tau}) \cap (r_3 + \tilde{\tau}', r_4 + \tilde{\tau}')| \ge \hat{h}.$$

So, there exists a coupling of $(\xi^w_{n_0+2k_0}, \tilde{\tau} + \tau^w_{n_0+2k_0})$ and $(\xi^{w'}_{n_0+2k_0}, \tilde{\tau}' + \tau^{w'}_{n_0+2k_0})$ such that

$$\mathbf{P}[E_1] \ge |\Delta^{\varepsilon}_{x_1}|\hat{h}, \tag{35}$$

where

$$E_1 = \{\xi^w_{n_0+2k_0} = \xi^{w'}_{n_0+2k_0} \text{ and } \tilde{\tau} + \tau^w_{n_0+2k_0} = \tilde{\tau}' + \tau^{w'}_{n_0+2k_0}\}$$

(one can use e.g. the *maximal coupling*, cf. Section 4 of Chapter 1 of [28]). On the event E_1, define $\hat{T} = \tilde{\tau} + \tau^w_{n_0+2k_0}$.

Suppose that the event E_1 does not occur. Consider two cases: $\tilde{\tau} + \tau^w_{n_0+2k_0} \le \tilde{\tau}' + \tau^{w'}_{n_0+2k_0}$ and $\tilde{\tau} + \tau^w_{n_0+2k_0} > \tilde{\tau}' + \tau^{w'}_{n_0+2k_0}$. In the first case, define

$$m_1 = \min\{n > n_0 + 2k_0 : \tilde{\tau} + \tau^w_n > \tilde{\tau}' + \tau^{w'}_{n_0+2k_0}\},$$

and $m'_1 = n_0 + 2k_0$. In the second case, define

$$m'_1 = \min\{n > n_0 + 2k_0 : \tilde{\tau}' + \tau^{w'}_n > \tilde{\tau} + \tau^w_{n_0+2k_0}\},$$

$m_1 = n_0 + 2k_0$ (i.e., we identify the process with the smaller local time, and let it evolve a few more steps so that its local time becomes close to the other process' local time). Clearly, in both cases we have

$$|(\tilde{\tau} + \tau^w_{m_1}) - (\tilde{\tau}' + \tau^{w'}_{m'_1})| \le \mathrm{diam}(\mathcal{D}).$$

Analogously, we obtain that one can couple $(\xi^w_{m_1+n_0+2k_0}, \tilde{\tau} + \tau^w_{m_1+n_0+2k_0})$ and $(\xi^{w'}_{m'_1+n_0+2k_0}, \tilde{\tau}' + \tau^{w'}_{m'_1+n_0+2k_0})$ in such a way that

$$\mathbf{P}[E_2 \mid E_1^c] \ge |\Delta^{\varepsilon}_{x_1}|\hat{h}, \tag{36}$$

where

$$E_2 = \{\xi^w_{m_1+n_0+2k_0} = \xi^{w'}_{m'_1+n_0+2k_0} \text{ and } \tilde{\tau} + \tau^w_{m_1+n_0+2k_0} = \tilde{\tau}' + \tau^{w'}_{m'_1+n_0+2k_0}\}.$$

On the event $E_1^c E_2$, define $\hat{T} = \tilde{\tau} + \tau^w_{m_1+n_0+2k_0}$.

Proceeding in this way, we construct two sequences of stopping times $(m_k, m'_k)_{k\geq 1}$ and a sequence of events

$$E_k = \{\xi^w_{m_k+n_0+2k_0} = \xi^{w'}_{m'_k+n_0+2k_0} \text{ and } \tilde{\tau} + \tau^w_{m_k+n_0+2k_0} = \tilde{\tau}' + \tau^{w'}_{m'_k+n_0+2k_0}\}$$

with the property (as in (35) and (36))

$$\mathbf{P}[E_k \mid E_1^c \dots E_{k-1}^c] \geq |\Delta^\varepsilon_{x_1}|\hat{h}; \tag{37}$$

on the event $E_1^c \dots E_{k-1}^c E_k$, we define $\hat{T} = \tilde{\tau} + \tau^w_{m_k+n_0+2k_0}$. Since,

$$\tau^w_{m_k} - \tau^w_{m_{k-1}} \geq 2(n_0 + 2k_0)\text{diam}(\mathcal{D}),$$

and, by (37)

$$\mathbf{P}[\text{none of the events } E_1, \dots, E_k \text{ occur}] \leq (1 - |\Delta^\varepsilon_{x_1}|\hat{h})^k,$$

we obtain that, for some β'_1, β'_2

$$\mathbf{P}[\hat{T} > t] \leq \frac{\beta'_1}{2} e^{-\beta'_2 t}. \tag{38}$$

Up to time $\hat{T}$, the processes X and X' can be explicitly constructed as in Section 2.2. Now, by definition we have that at time $\hat{T}$ the local times and the positions are the same for X and X', and so we have $X_{\hat{T}} = X'_{\hat{T}}$. Since also $X_{\hat{T}} \in \partial\mathcal{D}$, we can then construct the two realizations of KSB in such a way that $X_{\hat{T}+s} = X'_{\hat{T}+s}$ for all $s \geq 0$ (just use the same sequence of ηs from that moment on). This means that $\hat{T}$ is a coupling time, and, by Theorem 5.1 of Chapter 4 from [28], we obtain (10) from (38). This completes the proof of Theorem 2.2. □

Proof of Theorem 2.3. The family of functions $F_t : \bar{\mathcal{D}} \times \mathbb{S}^{d-1} \to \mathbb{R}$, $F_t(x, v) = \int_0^t \mathbf{E}_{x,v} f(X_s, V_s)\, ds$ is a Cauchy sequence with respect to the uniform norm $\|\cdot\|_\infty$, in view of (11) and (10). Hence it converges uniformly to a limit F, where

$$F(x, v) = \int_0^\infty \mathbf{E}_{x,v} f(X_s, V_s)\, ds. \tag{39}$$

Our interest for the limit is that

$$M_t = F(X_t, V_t) - \int_0^t f(X_s, V_s)\, ds$$

is a martingale, a fact which follows from (9) since F satisfies (8) by definition. We can compute the bracket $\langle M \rangle$ of the martingale M (that is, $\langle M \rangle$ is a predictable process, uniquely defined by the following: $\langle M \rangle_0 = 0$, and $M_t^2 - \langle M \rangle_t$ is a martingale)

$$\langle M \rangle_t = \sum_{n \geq 1} \mathbf{1}\{\tau_n \leq t\} \mathbf{E}_{x,v} \left([F(X_{\tau_n}, V_{\tau_n}) - F(X_{\tau_n}, V_{\tau_n^-})]^2 \mid \mathfrak{F}_{\tau_n^-} \right)$$

Now, with $N(t) \geq 1$ defined by $\tau_{N(t)-1} < t \leq \tau_{N(t)}$, we have

$$\begin{aligned} \frac{\langle M \rangle_t}{t} &= \frac{\tau_{N(t)}}{t} \frac{N(t)}{\tau_{N(t)}} \times \frac{1}{N(t)} \sum_{n=1}^{N(t)} \mathbf{E}_{x,v} \left([F(X_{\tau_n}, V_{\tau_n}) - F(X_{\tau_n}, V_{\tau_n^-})]^2 \mid \mathfrak{F}_{\tau_n^-} \right) \\ &\to \sigma_f^2 \quad \text{as } t \to \infty \end{aligned}$$

from Theorem 2.1, where

$$\sigma_f^2 = \frac{\mathbf{E}_{\hat{\mu}} \left([F(\xi_1, \ell_{\xi_1, \xi_2}) - F(\xi_1, \ell_{\xi_0, \xi_1})]^2 \right)}{\mathbf{E}_{\hat{\mu}} \|\xi_1 - \xi_0\|} \in [0, \infty). \tag{40}$$

By the central limit theorem for martingales [2, theorem 35.12], it follows that

$$t^{-1/2} M_t \to \text{Normal}(0, \sigma_f^2)$$

in law. Since F is bounded, we see that

$$t^{-1/2} \int_0^t f(X_s, V_s) ds = -t^{-1/2} M_t + \mathcal{O}(t^{-1/2}),$$

which implies the desired convergence and concludes the proof of Theorem 2.3.

Let us now prove that (12) implies that $\sigma_f^2 = 0$. For KSB, this function f is centered with respect to the uniform measure χ which is invariant. In this case, we can compute the function F from (39):

$$\begin{aligned} F(x,v) &= -\int_0^\infty \mathbf{E}_{x,v} V_s \cdot \nabla G(X_s) ds \\ &= -\lim_{t \to \infty} \mathbf{E}_{x,v} \int_0^t V_s \cdot \nabla G(X_s) ds \\ &= G(x) - \lim_{t \to \infty} \mathbf{E}_{x,v} G(X_t) \end{aligned}$$

$$= G(x) - \int_{\mathcal{D}\times\mathbb{S}^{d-1}} G(x)\chi(dx,dv)$$

which does not depend on v. Hence $F(x,\cdot)$ is constant on $\mathbb{S}_{\mathbf{n}(x)}$, and the definition (40) shows that $\sigma_f^2 = 0$. This can be understood in a different manner by computing

$$\begin{aligned} M_t &= G(X_t) + \int_0^t V_s \cdot \nabla G(X_s) ds \\ &= G(x) - \int_{\mathcal{D}\times\mathbb{S}^{d-1}} G(x)\chi(dx,dv) \end{aligned}$$

Therefore,

$$\int_0^t f(X_s,V_s)ds = G(X_t) - G(x)$$

is bounded, which shows again that $\sigma_f^2 = 0$.

It is not clear to us if one can find a condition on f which is necessary and sufficient for $\sigma_f^2 = 0$. Notice however that if for a.e. $x \in \partial\mathcal{D}$, $F(x,\cdot)$ is constant on $\mathbb{S}_x$, then $\sigma_f^2 = 0$. □

Proof of Theorem 2.4. We identify the invariant measure χ appearing in (10). By theorems 2.2 and 2.1, we have for bounded continuous functions $f : \bar{\mathcal{D}} \times \mathbb{S}^{d-1} \to \mathbb{R}$ and starting from any initial condition,

$$\begin{aligned} \int_{\bar{\mathcal{D}}\times\mathbb{S}^{d-1}} f(x,v)\,dx\,dv &= \lim_{t\to\infty} t^{-1} \int_0^t \mathbf{E} f(X_s,V_s)\,ds \\ &= \lim_{n\to\infty} \mathbf{E}\tau_n^{-1} \sum_{k=1}^{n} \int_{\tau_{k-1}}^{\tau_k} f(X_s,V_s)\,ds \\ &= \left(\mathbf{E}_{\hat{\mu}}\|\xi_1 - \xi_0\|\right)^{-1} \mathbf{E}_{\hat{\mu}} \int_0^{\tau_1} f(\xi_0 + s\ell_{\xi_0,\xi_1})\,ds. \quad (41) \end{aligned}$$

The numerator in (41) is equal to

$$\begin{aligned} &\int_{\partial\mathcal{D}} \hat{\mu}(dz) \int_{\mathbb{S}_{\mathbf{n}(z)}} dv\, \bar{\gamma}(U_z^{-1}v) \int_0^\infty ds f(z+sv,v)\mathbf{1}\{z \leftrightarrow z+sv\} \\ &= \int_{\mathcal{D}} dx \int_{\partial\mathcal{D}} dz \|z-x\|^{-d+1} \frac{d\hat{\mu}}{dz}(z)\bar{\gamma}(U_z^{-1}\ell_{z,x}) f(x,\ell_{z,x})\mathbf{1}\{z \leftrightarrow x\} \end{aligned}$$

with the change from polar coordinates (s, v) around z to Cartesian coordinates x. Then, by performing the change of variables from $z \in \partial\mathcal{D}$ to $v = \ell_{z,x} \in \mathbb{S}^{d-1}$, the Hausdorff measure integrator $dz\|z-x\|^{-d+1}$ becomes the Haar measure integrator $dv/\cos\varphi_z(v)$ with $z = \mathsf{h}_x(-v)$, and the whole integral becomes

$$\int_{\mathcal{D}} dx \int_{\mathbb{S}^{d-1}} dv f(x,v) \frac{d\hat{\mu}}{dz}(\mathsf{h}_x(-v)) \frac{\bar{\gamma}(U^{-1}_{\mathsf{h}_x(-v)}v)}{\cos\varphi_{\mathsf{h}_x(-v)}(v)}.$$

This is indeed the formula claimed in Theorem 2.4. □

Proof of Theorem 2.5. Since the process $(\tilde{X}_t, \tilde{V}_t)_{t\in\mathbb{R}}$ is stationary and Markov, it is enough to show that $(\tilde{X}_0, \tilde{V}_0, \tilde{X}_t, \tilde{V}_t) \stackrel{\text{law}}{=} (\tilde{X}_t, -\tilde{V}_t, \tilde{X}_0, \tilde{V}_0)$ for all $t \geq 0$, i.e., that

$$\mathbf{E} f(\tilde{X}_0, \tilde{V}_0, \tilde{X}_t, \tilde{V}_t) = \mathbf{E} f(\tilde{X}_t, -\tilde{V}_t, \tilde{X}_0, -\tilde{V}_0) \tag{42}$$

for all smooth test functions f on $\mathcal{D} \times \mathbb{S}^{d-1} \times \mathcal{D} \times \mathbb{S}^{d-1}$. Since

$$\mathbf{E} f(\tilde{X}_0, \tilde{V}_0, \tilde{X}_t, \tilde{V}_t) = \sum_{n\geq 0} \mathbf{E}\left[f(\tilde{X}_0, \tilde{V}_0, \tilde{X}_t, \tilde{V}_t) \mathbf{1}\{\tau_n \leq t < \tau_{n+1}\}\right]$$

this equality (42) will follow from the relation

$$\begin{aligned} &\mathbf{E}\Big[f(\tilde{X}_0, \tilde{V}_0, \tilde{X}_t, \tilde{V}_t) \mathbf{1}\{\tau_n \leq t < \tau_{n+1}\}\Big] \\ &\quad = \quad \mathbf{E}\Big[f(\tilde{X}_t, -\tilde{V}_t, \tilde{X}_0, -\tilde{V}_0) \mathbf{1}\{\tau_n \leq t < \tau_{n+1}\}\Big] \end{aligned} \tag{43}$$

for $n = 0, 1, \ldots$. The case $n = 0$ being clear, we now consider the case $n \geq 1$. The left-hand side of (43) is equal to

$$\int_{A_n} dx\, dv\, dy_2 \ldots dy_{n+1} \tilde{K}(y_1, y_2) \ldots \tilde{K}(y_n, y_{n+1}) f(x, v, y_n + R\ell_{y_n, y_{n+1}}, \ell_{y_n, y_{n+1}})$$

where $y_1 = \mathsf{h}_x(v)$, where R is the function of $x, y_1, \ldots, y_n$ given by

$$R = t - s_{1,n} - \|y_1 - x\|\,, \quad s_{k,n} = \|y_{k+1} - y_k\| + \ldots + \|y_n - y_{n-1}\|\,,$$

and $A_n \subset \mathcal{D} \times \mathbb{S}^{d-1} \times (\partial\mathcal{D})^n$ is defined by $\|y_1 - x\| + s_{1,n} \leq t < \|y_1 - x\| + s_{1,n+1}$. Changing the Cartesian variable x into the polar coordinates s, w around y_1, $s \in [0, \|y_1 - y_0\|], w \in \mathbb{S}^{d-1}$ (y_0 being defined as $y_0 = \mathsf{h}_x(-v)$), we write

$$dv\, dx \quad = \quad dv \|y_1 - y_0\|^{d-1} \mathbf{1}\{s \leq \|y_1 - y_0\|\} dw\, ds$$

$$
\begin{aligned}
&= dw \frac{\|y_1 - y_0\|^{d-1}}{\cos\varphi_{y_1}(w)} dv \frac{\|y_1 - y_0\|^{d-1}}{\cos\varphi_{y_0}(v)} \tilde{K}(y_0, y_1) \mathbf{1}\{s \le \|y_1 - y_0\|\} ds \\
&= dy_0\, dy_1 \tilde{K}(y_0, y_1) \mathbf{1}\{s \le \|y_1 - y_0\|\} ds
\end{aligned}
$$

in terms of the Hausdorff measure on $\partial\mathcal{D}$. Finally, the left-hand side of (43) writes

$$
\begin{aligned}
\int_{R \le \|y_{n+1} - y_n\|, s \le \|y_1 - y_0\|} & dy_0 \dots dy_{n+1}\, ds \tilde{K}(y_0, y_1) \dots \tilde{K}(y_n, y_{n+1}) \\
& \times f\left(y_1 - s\ell_{y_0,y_1}, \ell_{y_0,y_1}, y_n + R\ell_{y_n,y_{n+1}}, \ell_{y_n,y_{n+1}}\right)
\end{aligned}
$$

with R defined by $R + s + s_{1,n} = t$. Defining now S by $S + r + s_{1,n} = t$, and changing variables to $r = R, z_0 = y_{n+1}, \dots z_{n+1} = y_0$, the integral becomes

$$
\begin{aligned}
\int_{S \le \|z_{n+1} - z_n\|, r \le \|z_1 - z_0\|} & dy_0 \dots dy_{n+1}\, ds \tilde{K}(z_1, z_0) \dots \tilde{K}(z_{n+1}, z_n) \\
& \times f\left(z_n + S\ell_{z_n,z_{n+1}}, -\ell_{z_n,z_{n+1}}, \ell_{y_0,y_1}, z_1 - r\ell_{y_0,y_1}, -\ell_{y_0,y_1}\right)
\end{aligned}
$$

which is the right-hand side of (43) since $\tilde{K}$ is a symmetric function. This ends the proof. □

6 Proofs of geometric properties of the random chord

Proof of Theorem 2.6. To keep the paper self-contained, we provide the proof here, even though there are a lot of similarities with the proof of corresponding results in [4, 11, 19].

Let us start the process from the uniform distribution on $\partial\mathcal{D}$ (recall that it is the stationary distribution for KRW). Using (10) and the ergodic theorem one can write that

$$
\begin{aligned}
\frac{|A|}{|\mathcal{D}|} &= \lim_{t\to\infty} t^{-1} \int_0^t \mathbf{1}\{\tilde{X}_s \in A\}\, ds \\
&= \lim_{n\to\infty} \tau_n^{-1} \int_0^{\tau_n} \mathbf{1}\{\tilde{X}_s \in A\}\, ds \\
&= \lim_{n\to\infty} \left(n^{-1} \sum_{i=1}^n (\tau_i - \tau_{i-1})\right)^{-1} n^{-1} \sum_{i=1}^n \int_{\tau_{i-1}}^{\tau_i} \mathbf{1}\{\tilde{X}_s \in A\}\, ds
\end{aligned}
$$

$$= \bar{\mathfrak{m}}^{-1}\mathfrak{m}(A),$$

so we already obtain that $\mathfrak{m}(A)$ is proportional to $|A|$ (with a factor that does not depend on A):

$$\mathfrak{m}(A) = \frac{\bar{\mathfrak{m}}}{|\mathcal{D}|}|A|. \tag{44}$$

To calculate the value of the factor $\frac{\bar{\mathfrak{m}}}{|\mathcal{D}|}$, take any $x \in \mathcal{D}$ and a small $\delta > 0$ (so that $\mathcal{B}(x,\delta) \subset \mathcal{D}$). For any $u \in \mathbb{S}^{d-1}$ denote by

$$G_u = \{y \in \partial\mathcal{D} : \text{ there is } s > 0 \text{ such that } y + su \in \mathcal{B}(x,\delta) \text{ and } y \leftrightarrow y + su\}$$

the projection of $\mathcal{B}(x,\delta)$ in the $(-u)$-direction. For $y \in \mathbb{R}^d$ let

$$H_{y,u} = |\{s : y + su \in \mathcal{B}(x,\delta)\}|$$

be the length of the intersection of the ray drawn from y in the u-direction with $\mathcal{B}(x,\delta)$. Then

$$\begin{aligned}
\mathfrak{m}(\mathcal{B}(x,\delta)) &= \frac{1}{|\partial\mathcal{D}|}\int_{\partial\mathcal{D}} dy \int_{\mathbb{S}_{\mathbf{n}(y)}} \gamma_d \cos\varphi_y(u) H_{y,u}\, du \\
&= \frac{\gamma_d}{|\partial\mathcal{D}|}\int_{\mathbb{S}^{d-1}} du \int_{G_u} \cos\varphi_y(u) H_{y,u}\, dy.
\end{aligned} \tag{45}$$

For almost all $u \in \mathbb{S}^{d-1}$ there exists an unique $y_u \in \partial\mathcal{D}$ that "sees x in direction u", i.e., $\{y_u \leftrightarrow x\}$ and there exists $t_u > 0$ such that $y_u + t_u u = x$. Define by

$$\hat{G}_u = \{z \in \mathbb{R}^d : (z - y_u)\cdot \ell_{y_u,x} = 0, \text{ there is } s > 0 \text{ such that } y + su \in \mathcal{B}(x,\delta)\}$$

the projection of $\mathcal{B}(x,\delta)$ onto the hyperplane that passes through y_u and is perpendicular to $\ell_{y_u,x}$. Then, provided that $\cos\varphi_{y_u}(u) > 0$,

$$\begin{aligned}
\int_{G_u} \cos\varphi_y(u) H_{y,u}\, dy &= \int_{G_u} (\cos\varphi_{y_u}(u) + O(\delta)) H_{y,u}\, dy \\
&= \int_{\hat{G}_u} (1 + O(\delta)) H_{z,u}\, dz \\
&= |\mathcal{B}(x,\delta)|(1 + O(\delta)),
\end{aligned}$$

so (44) and (45) imply that

$$\frac{\bar{\mathfrak{m}}}{|\mathcal{D}|} = \frac{\gamma_d |\mathbb{S}^{d-1}|}{|\partial\mathcal{D}|},$$

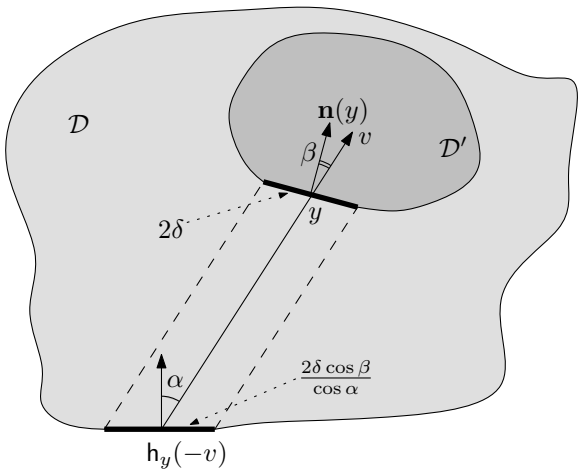

Figure 10: On the proof of Theorem 2.7

and we finally obtain (14) from (44). □

Proof of Theorem 2.7. First, we observe that the boundary of any convex domain is almost everywhere continuously differentiable. Indeed, since the boundary of a convex domain is locally a graph of a convex function, this follows from Theorems D and E of Section 44 of [24].

Consider a point $y \in \partial\mathcal{D}'$ where $\partial\mathcal{D}'$ has a locally $\mathcal{C}^1$ parametrization. As before, denote by

$$G'_u = \{z \in \partial\mathcal{D} : \text{ there is } s > 0 \text{ such that } z + su \in \partial\mathcal{D}' \cap \mathcal{B}(y,\delta), z \leftrightarrow z + su\}$$

the projection of $\partial\mathcal{D}' \cap \mathcal{B}(y,\delta)$ onto $\partial\mathcal{D}$ in the $(-u)$-direction. Let $I = \{[\Xi_1,\Xi_2] \cap \mathcal{D}' \neq \emptyset\}$ be the event that the random $\mathcal{D}$-chord intersects $\mathcal{D}'$. For $B \subset \mathbb{S}_{\mathbf{n}(y)}$, write (cf. Figure 10, and note that $\ell_{\Xi_2,\Xi_1} = \ell_{\Xi'_2,\Xi'_1}$)

$$\begin{aligned}
&\mathbf{P}[\Xi'_1 \in \mathcal{B}(y,\delta), \ell_{\Xi'_2,\Xi'_1} \in B] \\
&\quad = \mathbf{P}[\Xi_1 \in G'_{\ell_{\Xi_2,\Xi_1}}, \ell_{\Xi_2,\Xi_1} \in B \mid I] \\
&\quad = \mathbf{P}[\Xi_1 \in G'_{\ell_{\Xi_2,\Xi_1}}, \ell_{\Xi_2,\Xi_1} \in B] \times \mathbf{P}(I)^{-1} \\
&\quad = \frac{\gamma_d}{|\partial\mathcal{D}|\ \mathbf{P}(I)} \int_B dv \int_{G'_v} \cos\varphi_x(v)\, dx \\
&\quad = \frac{\gamma_d}{|\partial\mathcal{D}|\ \mathbf{P}(I)} (|\partial\mathcal{D}' \cap \mathcal{B}(y,\delta)| + o(\delta^{d-1})) \int_B \cos\varphi_y(v)\, dv.
\end{aligned}$$

This shows in fact that the couple $(\Xi'_1, \ell_{\Xi'_2,\Xi'_1})$ has a density with respect to $dy\,dv$ which is proportional to $\cos\varphi_y(v)\mathbf{1}\{\mathbb{S}_{\mathbf{n}(y)}\}$, i.e.,

$$\mathbf{P}[\Xi'_1 \in \mathcal{B}(y,\delta), \ell_{\Xi'_2,\Xi'_1} \in B] = \frac{\gamma_d}{|\partial\mathcal{D}|\,\mathbf{P}(I)} \int_{(\partial\mathcal{D}'\cap\mathcal{B}(y,\delta))\times B} \cos\varphi_x(v)\,dx\,dv, \quad (46)$$

which proves Theorem 2.7. □

Remark. We can also identify the normalization in the last formula,

$$\mathbf{P}(I) = \frac{|\partial\mathcal{D}'|}{|\partial\mathcal{D}|}. \quad (47)$$

Proof of Theorem 2.8. Let $y \in \partial\mathcal{D}'$ where $\partial\mathcal{D}'$ has a locally $\mathcal{C}^1$ parametrization, $\delta > 0$ and a Borel set $B \subset \mathbb{S}_{\mathbf{n}(y)}$. Similarly to (46), we get

$$\mathbf{P}\Big[\exists k \le \iota : \Xi'_{1,k} \in \mathcal{B}(y,\delta), \ell_{\Xi'_{2,k},\Xi'_{1,k}} \in B\Big] = \frac{\gamma_d}{|\partial\mathcal{D}|} \int_{(\partial\mathcal{D}'\cap\mathcal{B}(y,\delta))\times B} \cos\varphi_x(v)\,dx\,dv. \quad (48)$$

Note that left-hand side can be written as

$$\mathbf{E}\Big[\sum_{k=1}^{\iota} \mathbf{1}\{\Xi'_{1,k} \in \mathcal{B}(y,\delta), \ell_{\Xi'_{2,k},\Xi'_{1,k}} \in B\}\Big].$$

Then, for $A_1, A_2 \in \partial\mathcal{D}'$ such that $A_1 \cap A_2 = \emptyset$ and $x \leftrightarrow y$ in $\mathcal{D}'$ for all $x \in A_1, y \in A_2$, we get

$$\mathbf{E}\Big[\sum_{k=1}^{\iota} \mathbf{1}\{\Xi'_{1,k} \in A,\, \Xi'_{2,k} \in B\}\Big] = \frac{1}{|\partial\mathcal{D}|} \int_{A\times B} \tilde{K}(x,y)\,dx\,dy.$$

This is enough to ensure that, for $C \subset \partial\mathcal{D}' \times \partial\mathcal{D}'$, we have

$$\mathbf{E}\Big[\sum_{k=1}^{\iota} \mathbf{1}\{(\Xi'_{1,k}, \Xi'_{2,k}) \in C\}\Big] = \frac{1}{|\partial\mathcal{D}|} \int_{C} \tilde{K}(x,y)\,dx\,dy.$$

which proves (16). Taking $C = \partial\mathcal{D}' \times \partial\mathcal{D}'$ in (16), we obtain (17). □

Proof of Theorem 2.9. For any $v \in \mathbb{S}_e$ and $\delta > 0$ define

$$S_v(\delta) = \{z \in \mathbb{R}^d : \text{ there exist } t \in [-\delta,\delta], x \in S \text{ such that } z + tU_x v = x\}.$$

Note that

$$|S_v(\delta)| = 2\delta(1+o(\delta))|S|\cos\varphi(e,u). \tag{49}$$

Let us consider first the process in the stationary regime, i.e., we suppose that $\tilde{X}_0, \tilde{V}_0$ (and hence $\tilde{X}_t, \tilde{V}_t$) are independent and uniform. For $\delta < \inf_{x\in\partial\mathcal{D}, y\in S}\|x-y\|$ write (observe that the next probability does not depend on t)

$$\begin{aligned}
&\mathbf{P}[\text{there exists } n \text{ such that } \hat{\tau}_n \in [t, t+\delta], w_n \in B] \\
&= \mathbf{P}[\tilde{X}_t \in S_{\tilde{V}_t}(\delta)] \\
&= \frac{1}{|\mathbb{S}^{d-1}|}\int_B \mathbf{P}[\tilde{X}_t \in S_u(\delta) \mid \tilde{V}_t = u]\, du \\
&= \frac{1}{|\mathbb{S}^{d-1}|}\int_B \mathbf{P}[\tilde{X}_t \in S_u(\delta)]\, du \\
&= \delta(1+o(\delta))|S|\frac{2}{|\mathbb{S}^{d-1}|}\int_B \cos\varphi(e,u)\, du.
\end{aligned}$$

This implies (18) for the stationary case. For the general case, the formula (18) now easily follows from Theorem 2.2. □
